# Chapter 0

## Background & Review

Everything mentioned in this chapter should already be familiar to you from other math classes. These topics span two main areas: algebra/pre-calculus and single variable calculus. Ideas from algebra and pre-calculus will be used either implicitly or with only a passing reference. Topics from single variable calculus will mostly be used in setting up problems.

If you are unfamiliar with anything mentioned, you can use many of the great online resources like Khan Academy, to familiarize yourself before moving forward.

### 0.1 Algebra and Pre-Calculus

#### 0.1.1 Sets

**Definition.** A set  $A$  is a collection of distinct elements. Those elements can be anything, like numbers, functions, and even other sets.

We can define a set by giving its elements, like  $A = \{-2, 5, 3\}$  or by describing its properties, like  $A = \{x \mid x > 0\}$  where the vertical bar means “such that”. If an object  $x$  is a member of the set  $A$ , we write  $x \in A$ .

A set  $A$  is called a subset of a set  $B$  if every element of  $A$  is also an element of  $B$ . We can write this as  $A \subseteq B$ . For example,  $\{7, 10, 16\} \subseteq \{5, 6, 7, 9, 10, 11, 16\}$ . Note that this relation can be strict if there exists at least one element in  $B$  that is not also an element of  $A$ . Some common sets and their informal definitions are given below:

Set Name	Symbol	Informal Definition
Natural numbers	$\mathbb{N}$	$\{1, 2, 3, \dots\}$
Integers	$\mathbb{Z}$	$\{\dots, -3, -2, -1, 0, 1, 2, 3, \dots\}$
Rational numbers	$\mathbb{Q}$	$\{\frac{m}{n} \mid m, n \in \mathbb{Z} \text{ and } n \neq 0\}$
Real numbers	$\mathbb{R}$	Any number on the number line <sup>1</sup>

This means that  $\mathbb{N} \subset \mathbb{Z} \subset \mathbb{Q} \subset \mathbb{R}$ .

There are several common operations that can be performed on sets. The union  $A \cup B$  of two sets  $A$  and  $B$  is the set of all elements that are elements of  $A$  or of  $B$ . Similarly, the intersection  $A \cap B$  of two sets  $A$  and  $B$  is the set of all elements that are also elements of both  $A$  and  $B$ .

**Example.** If  $A = \{\sqrt{2}, 2, 5, 8\}$  and  $B = \{-9, 8, 2.3\}$ , what are  $A \cup B$  and  $A \cap B$ ?

To find the union, we combine the sets, making sure to include any repeated element only once:

$$A \cup B = \{-9, \sqrt{2}, 2, 2.3, 5, 8\}.$$

Then, since the only element both sets share is 8, we also have

$$A \cap B = \{8\}.$$

### 0.1.2 Intervals

**Definition.** We call a subset  $I$  of  $\mathbb{R}$  an interval if, for any  $a, b \in I$  and  $x \in \mathbb{R}$  such that  $a \leq x \leq b$ , then  $x \in I$ .

We can write an interval more simply using the notation  $[a, b]$ , which is equivalent to  $\{x \in \mathbb{R} \mid a \leq x \leq b\}$ . This is called a closed interval, and to make the inequalities strict, we can also define an open interval by using parantheses instead of square brackets.

In addition, we can mix the two to create half-open intervals, where one inequality is strict and the other isn't. For instance,  $(2, 5]$  refers to the set  $\{x \in \mathbb{R} \mid x < 2 \leq 5\}$ . Finally, if the interval is unbounded in either direction, we use the notations  $-\infty$  and  $\infty$  to indicate that there is no minimum or maximum, respectively.

**Example.** Is  $8 \in (-\infty, 4) \cup [8, 100)$ ?

Since  $8 \leq 8 < 100$  is a true statement,  $8 \in [8, 100)$ . Since we are taking the union with another set, all of the members of the right interval will also be members of the union of intervals. Therefore, the statement is true.

### 0.1.3 Functions

**Definition.** A function  $f$  is a rule between a pair of sets, denoted  $f : D \rightarrow C$ , that assigns values from the first set, the domain  $D$ , to the second set, the codomain  $C$ .

We call the subset of the codomain  $C$  that constitutes all values  $f$  can actually attain the range  $R \subseteq C$ . Note that when we draw a graph of a function, all we are doing is drawing all ordered pairs  $\{(x, f(x)) \mid x \in D\}$ .

**Example.** Find the domain of the following function:

$$f(x) = \frac{1}{(1-x)\sqrt{5-x^2}}$$

We know that  $\frac{n}{0}$  is undefined for all  $n \in \mathbb{R}$  and  $\sqrt{x}$  is only defined for  $x \geq 0$ . The first condition applies to the first term in the denominator and both conditions apply to the second, giving us

$$(1-x) \neq 0 \text{ and } 5-x^2 > 0$$

The first condition implies  $x \neq 1$  while the second implies  $|x| < \sqrt{5}$ . Putting these together, we find that the domain is

$$\{x \mid x \neq 1, |x| < \sqrt{5}\} \text{ or } (-\sqrt{5}, 1) \cup (1, \sqrt{5})$$

We can also compose two functions, such that the output of one function is the input of another:

$$(f \circ g)(x) = f(g(x)).$$

**Definition.** A function  $g$  is called an inverse function of  $f$  if  $f(g(x)) = x$  for all  $x$  in the domain of  $g$  and  $g(f(x)) = x$  for all  $x$  in the domain of  $f$ . We write this as  $g = f^{-1}$ .

One common algorithm for finding an inverse function is to set  $y = f(x)$ , substitute all  $x$ 's for  $y$ 's, and then solve for  $y$ .

**Example.** Find the inverse function of

$$f(x) = \frac{5x+2}{4x-3}.$$

We first make the substitutions to set up the algorithm:

$$y = \frac{5x+2}{4x-3} \text{ followed by } x = \frac{5y+2}{4y-3}$$

After multiplying both sides by the denominator and simplifying, we have

$$\implies 4xy - 3x = -5y - 2 \implies y = f^{-1}(x) = \frac{3x-2}{4x+5}.$$

We say that a function  $f$  is even if it satisfies  $f(-x) = f(x)$  for all  $x \in D$ . Likewise, we say that a function  $f$  is odd if it satisfies  $f(-x) = -f(x)$  for all  $x \in D$ . Geometrically, we can see that the graph of an even function is symmetric with respect to the  $y$ -axis, while the graph of an odd function is symmetric with respect to the origin.

**Example.** Is  $f(x) = 2x - x^2$  even, odd, or neither?

We see that

$$f(-x) = 2(-x) - (-x)^2 = -2x - x^2.$$

Since  $f(-x) \neq f(x)$  and  $f(-x) \neq -f(x)$ , the function is neither even nor odd.

### 0.1.4 Complex Numbers

**Definition.**  $i$  is called the imaginary unit. It's defined by  $i^2 = -1$ .

The set of complex numbers ( $\mathbb{C}$ ) is an extension of the real numbers. Complex numbers have the form  $z = \alpha + \beta i$ , where  $\alpha$  and  $\beta$  are real numbers. The  $\alpha$  part of  $z$  is called the real part, so  $\Re(z) = \alpha$ . The  $\beta$  part of  $z$  is called the imaginary part, so  $\Im(z) = \beta i$ .

Often, complex numbers are visualized as points or vectors in a 2D plane, called the complex plane, where  $\alpha$  is the x-component, and  $\beta$  is the y-component. Thinking of complex numbers like points helps us define the magnitude of complex numbers and compare them. Since a point  $(x, y)$  has a distance  $\sqrt{x^2 + y^2}$  from the origin, we can say the magnitude of  $z$ ,  $|z|$  is  $\sqrt{\alpha^2 + \beta^2}$ . Thinking of complex numbers like vectors helps us understand adding two complex numbers, since you just add the components like vectors.

A common operation on complex numbers is the complex conjugate. The complex conjugate of  $z = \alpha + \beta i$  is  $\bar{z} = \alpha - \beta i$ .  $z$  and  $\bar{z}$  are called a conjugate pair.

Conjugate pairs have the following properties. Let  $z, w \in \mathbb{C}$  and  $n \in \mathbb{Z}$ .

$$\begin{aligned}\overline{z \pm w} &= \bar{z} \pm \bar{w} \\ \overline{zw} &= \bar{z} \cdot \bar{w} \\ \bar{\bar{z}} &= z \Leftrightarrow z \in \mathbb{R} \\ z\bar{z} &= |z|^2 = |\bar{z}|^2 \\ \overline{\bar{z}} &= z \\ \bar{z}^n &= \overline{z^n} \\ z^{-1} &= \frac{\bar{z}}{|z|^2}\end{aligned}$$

### 0.1.5 Factoring Polynomials

We want to break up a polynomial like  $f(x) = a_0 + a_1x^1 + \dots + a_nx^n$  into linear factors so that  $f(x) = c(x - b_1) \cdot \dots \cdot (x - b_n)$ . This form makes it simple to see that the roots of  $f$ , solutions to  $f(x) = 0$ , are  $x = b_1 \dots b_n$ .

For quadratics,  $f(x) = ax^2 + bx + c$ , there exists a simple formula that will give us both roots, the quadratic formula

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.$$

We can see that when  $b^2 - 4ac < 0$ , like for  $f(x) = x^2 + 5x + 10$ , we will get complex roots  $\alpha \pm \beta i$ . For any polynomial, these roots come in pairs, so if  $\alpha + \beta i$  is a root, then so is  $\alpha - \beta i$ . This means that every conjugate pair  $\alpha \pm \beta i$  has a quadratic equation with those roots. Sometimes we will not

factor quadratics with complex roots into linear terms.

Although there do exist explicit formulas for finding roots for cubic (degree 3) and quartic (degree 4) equations, they are too long and not useful enough to memorize. When working by hand, we instead use other tricks to find roots.

There are a few useful tricks that can help. If the polynomial doesn't have a constant term, then 0 is a root. If all the coefficients sum to 0, then 1 is a root. For certain polynomials with an even number of terms, like all cubics of the form  $ax^3 + bx^2 + cax + cb$  we can factor out a term from the first two and last two terms to get  $x^2(ax + b) + c(ax + b) = (ax + b)(x^2 + c)$ . For other polynomials, we might just try guessing and checking values. However, we need a more efficient way that works in general.

Since we are looking to find linear factors  $f(x) = (x - b_1) \cdot \dots \cdot (x - b_n)$ , we can see that the constant term in the polynomial is the product of the roots  $b_1 \cdot \dots \cdot b_n$ . In fact, since the coefficients of polynomials are completely determined by the roots and the leading coefficient, all the coefficients are sums and products of roots. You might remember when factoring quadratics that the coefficient of  $x$  term is the sum of the two roots. These rules are called Vieta's formulas.

So, if we have the constant term, we can check all of its integer factors to see if any are roots. For each root, we can divide, using a technique like synthetic division, to continue finding the rest of the roots. This method is especially useful on tests because the roots tend to be integers.

**Example.** Factor the polynomial  $x^5 + x^4 - 2x^3 + 4x^2 - 24x$ .

We can immediately see that there is no constant term, so  $x = 0$  is a root. Now we need to work on factoring  $x^4 + x^3 - 2x^2 + 4x - 24$ .

The factors of -24 are: -24, -12, -8, -6, -4, -3, -2, -1, 1, 2, 3, 4, 6, 8, 12, and 24. Starting from roots close to 0 and working outwards, we find that  $x = 2$  is a root. So, we synthetic divide like so

$$\begin{array}{r|rrrrr} x = 2 & 1 & 1 & -2 & 4 & -24 \\ & \downarrow & 2 & 6 & 8 & 24 \\ \hline & 1 & 3 & 4 & 12 & 0 \end{array}$$

to see that now we need to work on factoring  $x^3 + 3x^2 + 4x + 12$ .  $x^3 + 3x^2 + 4x + 12 = x^2(x + 3) + 4(x + 3) = (x + 3)(x^2 + 4)$ , so  $x = -3$  is a root, and we need to work on factoring  $x^2 + 4$ .  $x^2 + 4$  has two complex roots  $\pm 2i$ , so we'll leave it as a quadratic.

$$x^5 + x^4 - 2x^3 + 4x^2 - 24x = x(x - 2)(x - 3)(x^2 + 4)$$

## 0.1.6 Trig Functions & The Unit Circle

Imagine a circle of radius 1 centered at the origin that we'll call the unit circle. The  $x$  and  $y$  coordinates of a point on the unit circle are completely determined by the angle  $\theta$  in radians between the

$x$ -axis and a line from the origin to the point.

The function  $\cos \theta$  tells us  $x$ -coordinate of the point, while  $\sin \theta$  tells us the  $y$ -coordinate of the point. The function  $\tan \theta = \frac{\sin \theta}{\cos \theta}$  tells us the slope of the line from the origin to the point. Most of the trig functions have geometric interpretations as shown below. The most used ones are  $\sin$ ,  $\cos$ ,  $\tan = \frac{\sin}{\cos}$ ,  $\cot = \frac{\cos}{\sin}$ ,  $\csc = \frac{1}{\sin}$ , and  $\sec = \frac{1}{\cos}$ .

Figure 1: Wikipedia - Unit circle

We can also think about the inverses of these trig functions. These are either notated with a -1 exponent on the function, or the prefix arc in front of the function name. Many of these functions are only defined on a part of the domain  $[0, 2\pi]$ . Below is a table of the inverse trig functions and their domains.

Function	Domain
$\arcsin$	$[-1, 1]$
$\arccos$	$[-1, 1]$
$\arctan$	$(-\infty, \infty)$
$\text{arccot}$	$(-\infty, \infty)$
$\text{arccsc}$	$(-\infty, -1] \cup [1, \infty)$
$\text{arcsec}$	$(-\infty, -1] \cup [1, \infty)$

### 0.1.7 Trig Identities

As we could see in Figure 0.1.6,  $\sin$  and  $\cos$  form a right triangle with hypotenuse 1. So, using the Pythagorean Theorem,

$$\sin^2 \theta + \cos^2 \theta = 1.$$

By dividing by  $\sin^2$  or  $\cos^2$ , we can also get

$$1 + \cot^2 \theta = \csc^2 \theta \text{ and } \tan^2 \theta + 1 = \sec^2 \theta.$$

Together, these 3 identities are called the Pythagorean Identities.

We can also relate functions and co-functions.

$$\sin(\theta) = \cos\left(\frac{\pi}{2} - \theta\right).$$

Some of the most useful and used identities are the sum and difference.

$$\begin{aligned}\sin(\alpha \pm \beta) &= \sin \alpha \cos \beta \pm \cos \alpha \sin \beta \\ \cos(\alpha \pm \beta) &= \cos \alpha \cos \beta \mp \sin \alpha \sin \beta \\ \tan(\alpha \pm \beta) &= \frac{\tan \alpha \pm \tan \beta}{1 \mp \tan \alpha \tan \beta} \\ \sin \alpha \pm \sin \beta &= 2 \sin\left(\frac{\alpha \pm \beta}{2}\right) \cos\left(\frac{\alpha \mp \beta}{2}\right) \\ \cos \alpha + \cos \beta &= 2 \cos\left(\frac{\alpha + \beta}{2}\right) \cos\left(\frac{\alpha - \beta}{2}\right) \\ \cos \alpha - \cos \beta &= -2 \sin\left(\frac{\alpha + \beta}{2}\right) \sin\left(\frac{\alpha - \beta}{2}\right)\end{aligned}$$

### 0.1.8 Exponentials & Logarithms

**Definition.**  $e$  is the base of the natural logarithm. It's defined by the limit

$$e = \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n}\right)^n.$$

The functions  $\exp x = e^x$  and  $\ln x$  are inverses of each other:

$$e^{\ln x} = x \text{ and } \ln e^x = x.$$

Just like other exponentials, the normal rules for adding, subtracting, and multiplying exponents apply:

$$e^x e^y = e^{x+y}, \frac{e^x}{e^y} = e^{x-y}, \text{ and } (e^x)^k = e^{xk}.$$

Similar rules apply for logarithms:

$$\ln x + \ln y = \ln xy, \ln x - \ln y = \ln\left(\frac{x}{y}\right), \text{ and } \ln(a^b) = b \ln a.$$

We can also write a logarithm of any base using natural logarithms:

$$\log_b a = \frac{\ln a}{\ln b}.$$

The number  $e$  is also unique in that it is the only real number  $a$  satisfying the equation

$$\frac{d}{dx} a^x = a^x,$$

meaning  $e^x$  is its own derivative.

## 0.1.9 Partial Fractions

If we have a function of two polynomials  $f(x) = \frac{P(x)}{Q(x)}$ , it's often easier to break this quotient into a sum of parts where the denominator is a linear or quadratic factor and the numerator is always a smaller degree than the denominator.

**Example.**

$$\frac{2x - 1}{x^3 - 6x^2 + 11x - 6} = \frac{1/2}{x - 1} + \frac{-3}{x - 2} + \frac{5/2}{x - 3}.$$

One natural way to find these small denominators comes from the linear factors of the denominator where we keep quadratics with complex roots. This way, when making a common denominator, we get back the original big denominator. However, there are a few special cases we have to take care of.

### Linear Factors

This is the the most basic type where the degree of the numerator is less than the degree of the denominator and the denominator factors into all linear factors with no repeated roots. In this case we can write

$$\frac{P(x)}{Q(x)} = \frac{A_1}{(x - a_1)} + \dots + \frac{A_n}{(x - a_n)}.$$

Multiplying each side by  $Q(x)$ ,

$$P(x) = A_1(x - a_2) \dots (x - a_n) + \dots + A_n(x - a_1) \dots (x - a_{n-1}).$$

We can then find each  $A_i$  by evaluating both sides at  $x = a_i$ , since every term except the  $i$ th has an  $(x - a_i)$  factor that will go to 0. So,

$$A_i = \frac{P(a_i)}{(x - a_i) \dots (x - a_{i-1})(x - a_{i+1}) \dots (x - a_n)}.$$

**Example.** Find the partial fraction decomposition of the following expression:

$$\frac{2x - 1}{x^3 - 6x^2 + 11x - 6}.$$

Factoring,

$$x^3 - 6x^2 + 11x - 6 = (x - 1)(x - 2)(x - 3).$$

So,

$$\frac{2x - 1}{x^3 - 6x^2 + 11x - 6} = \frac{A_1}{x - 1} + \frac{A_2}{x - 2} + \frac{A_3}{x - 3}.$$

Multiplying each side by the denominator,

$$2x - 1 = A_1(x - 2)(x - 3) + A_2(x - 1)(x - 3) + A_3(x - 1)(x - 2).$$

At  $x = 1$ ,

$$1 = A_1(1 - 2)(1 - 3) \implies A_1 = \frac{1}{2}.$$

At  $x = 2$ ,

$$3 = A_2(2 - 1)(2 - 3) \implies A_2 = -3.$$

At  $x = 3$ ,

$$5 = A_3(3 - 1)(3 - 2) \implies A_3 = \frac{5}{2}.$$

So,

$$\frac{2x - 1}{x^3 - 6x^2 + 11x - 6} = \frac{1/2}{x - 1} + \frac{-3}{x - 2} + \frac{5/2}{x - 3},$$

just as was shown in the previous example.

### Repeated Linear Factors

If  $Q(x)$  has repeated roots, it factors into

$$Q(x) = R(x)(x - a)^k, k \geq 2 \text{ and } R(a) \neq 0.$$

When making the common denominator for each repeated root of multiplicity  $k$ , we do

$$\frac{P(x)}{R(x)(x - a)^k} = (\text{Decomposition of } R(x)) + \frac{A_1}{x - a} + \dots + \frac{A_k}{(x - a)^k}.$$

You would then multiply each side by the denominator like in the linear factors case and solve for the coefficients. The only additional difficulty is that you might have to use previous results or solve a system of linear equations to get some of the constants.

**Example.** Find the partial fraction of the following expression:

$$\frac{x^2 + 5x - 6}{x^3 - 7x^2 + 16x - 12}.$$

Factoring,

$$x^3 - 7x^2 + 16x - 12 = (x - 3)(x - 2)^2.$$

So,

$$\frac{x^2 + 5x - 6}{x^3 - 7x^2 + 16x - 12} = \frac{A_1}{x - 3} + \frac{A_2}{x - 2} + \frac{A_3}{(x - 2)^2}.$$

Multiplying each side by the denominator,

$$x^2 + 5x - 6 = A_1(x - 2)^2 + A_2(x - 2)(x - 3) + A_3(x - 3).$$

At  $x = 2$ ,

$$8 = A_3(2 - 3) \implies A_3 = -8.$$

At  $x = 3$ ,

$$18 = A_1(3 - 2)^2 \implies A_1 = 18.$$

Now we'll use our results for  $A_1$  and  $A_3$  to find  $A_2$  using a value for  $x$  that isn't 2 or 3 so the  $A_2$  term doesn't become 0. A good choice is  $x = 0$ .

At  $x = 0$ ,

$$-6 = 18(0 - 2)^2 + A_2(0 - 2)(0 - 3) + -8(0 - 3) \implies A_2 = -17.$$

So,

$$\frac{x^2 + 5x - 6}{x^3 - 7x^2 + 16x - 12} = \frac{18}{x - 3} - \frac{17}{x - 2} - \frac{8}{(x - 2)^2}.$$

## Quadratic Factors

If a quadratic doesn't have real roots, then we have a quadratic factor. Here, we'll assume that the quadratic factor isn't repeated. So,  $Q(x) = R(x)(ax^2 + bx + c)$ ,  $b^2 - 4ac < 0$ , and  $R(x)$  is not evenly divisible by  $ax^2 + bx + c$ . In this case, we say

$$\frac{P(x)}{R(x)(ax^2 + bx + c)} = (\text{Decomposition of } R(x)) + \frac{A_1x + B_1}{ax^2 + bx + c}.$$

We then solve for the constants in the numerator, possibly having to solve a system of equations or using previous results and less convenient values for  $x$ .

**Example.** Find the partial fraction decomposition of the following expression:

$$\frac{6x^2 + 21x + 11}{x^3 + 5x^2 + 3x + 15}.$$

Factoring,

$$x^2 + 5x^2 + 3x + 15 = (x + 5)(x^2 + 3).$$

So,

$$\frac{6x^2 + 21x + 11}{x^3 + 5x^2 + 3x + 15} = \frac{A_1}{x + 5} + \frac{A_2x + B_2}{x^2 + 3}.$$

Multiplying each side by the denominator,

$$6x^2 + 21x + 11 = A_1(x^2 + 3) + (A_2x + B_2)(x + 5).$$

At  $x = -5$ ,

$$56 = 28A_1 \implies A_1 = 2.$$

Now we'll use the previous result and another value for  $x$ . We can use  $x = 0$  to not have to worry about the  $A_2$  term. At  $x = 0$ ,

$$11 = 2(3) + (B_2)(5) \implies B_2 = 1.$$

Now we'll use the previous 2 results to find  $A_2$ .  $x = 1$  is a good choice to keep the numbers small. At  $x = 1$ ,

$$38 = 2(1 + 3) + (A_2 + 1)(6) \implies A_2 = 4.$$

So,

$$\frac{6x^2 + 21x + 11}{x^3 + 5x^2 + 3x + 15} = \frac{2}{x + 5} + \frac{4x + 1}{x^2 + 3}.$$

## Repeated Quadratic Factors

If a quadratic factor that can't be broken into linear factors is repeated, then we can write  $Q(x) = R(x)(ax^2 + bx + c)^k$ ,  $k \geq 0$ , and  $R(x)$  is not divisible by  $(ax^2 + bx + c)^k$ . Now we have to do a combination of what we did for repeated linear factors and quadratic factors. We say

$$\frac{P(x)}{R(x)(ax^2 + bx + c)^k} = (\text{Decomposition of } R(x)) + \frac{A_1x + B_1}{ax^2 + bx + c} + \dots + \frac{A_kx + B_k}{(ax^2 + bx + c)^k}.$$

We then solve for the coefficients in the numerator.

**Example.** Find the partial fraction decomposition of the following expression:

$$\frac{3x^4 - 2x^3 + 6x^2 - 3x + 3}{x^5 + 3x^4 + 4x^3 + 12x^2 + 4x + 12}.$$

Factoring,

$$x^5 + 3x^4 + 4x^3 + 12x^2 + 4x + 12 = (x + 3)(x^2 + 2)^2.$$

So,

$$\frac{3x^4 - 2x^3 + 6x^2 - 3x + 3}{x^5 + 3x^4 + 4x^3 + 12x^2 + 4x + 12} = \frac{A_1}{x + 3} + \frac{A_2x + B_2}{x^2 + 2} + \frac{A_3x + B_3}{(x^2 + 2)^2}.$$

Multiplying each side by the denominator,

$$3x^4 - 2x^3 + 6x^2 - 3x + 3 = A_1(x^2 + 2)^2 + (A_2x + B_2)(x^2 + 2)(x + 3) + (A_3x + B_3)(x + 3).$$

At  $x = -3$ ,

$$363 = 121A_1 \implies A_1 = 3.$$

Now, we'll use our result for  $A_1$  and pick a value for  $x$  that minimizes the number of things we need to solve for. We'll have to solve a linear system with 4 unknowns, so we'll need up to 4 values.

At  $x = 0$ ,

$$3 = 3(2)^2 + B_2(2)(3) + B_3(3) \implies 2B_2 + B_3 = -3.$$

At  $x = 1$ ,

$$7 = 3(3)^2 + (A_2 + B_2)(3)(4) + (A_3 + B_3)(4) \implies 3A_2 + A_3 + 3B_2 + B_3 = -5.$$

At  $x = -1$ ,

$$17 = 3(3)^2 + (-A_2 + B_2)(3)(2) + (-A_3 + B_3)(2) \implies -3A_2 - A_3 + 3B_2 + B_3 = -5.$$

At  $x = 2$ ,

$$53 = 3(6)^2 + (2A_2 + B_2)(6)(5) + (2A_3 + B_3)(5) \implies 12A_2 + 2A_3 + 6B_2 + B_3 = -11.$$

Now we have the following system of equations:

$$\begin{cases} 0A_2 + 0A_3 + 2B_2 + B_3 &= -3 \\ 3A_2 + A_3 + 3B_2 + B_3 &= -5 \\ -3A_2 - A_3 + 3B_2 + B_3 &= -5 \\ 12A_2 + 2A_3 + 6B_2 + B_3 &= -11 \end{cases}.$$

Solving,

$$A_2 = 0, A_3 = 0, B_2 = -2, \text{ and } B_3 = 1.$$

So,

$$\frac{3x^4 - 2x^3 + 6x^2 - 3x + 3}{x^5 + 3x^4 + 4x^3 + 12x^2 + 4x + 12} = \frac{3}{x+3} - \frac{2}{x^2+2} + \frac{1}{(x^2+2)^2}.$$

## Improper Fractions

If the degree of the numerator is greater than or equal to the degree of the denominator, we have a case of improper fractions. In this case, we have to do polynomial long division to get a quotient and remainder and then decompose the remainder if necessary. So,

$$\frac{P(x)}{Q(x)} = R(x) + \frac{S(x)}{Q(x)}.$$

**Example.** Find the partial fraction decomposition of the following expression:

$$\frac{x^3 + 3}{x^2 - 2x - 3}.$$

First we do polynomial long division to find that

$$\frac{x^3 + 3}{x^2 - 2x - 3} = x + 2 + \frac{7x + 9}{x^2 - 2x - 3}.$$

Now that the numerator is of a lesser degree than the denominator, we can decompose it normally.

$$x^2 - 2x - 3 = (x - 3)(x + 1).$$

So,

$$\frac{7x + 9}{x^2 - 2x - 3} = \frac{A_1}{x - 3} + \frac{A_2}{x + 1}.$$

Multiplying each side by the denominator,

$$7x + 9 = A_1(x + 1) + A_2(x - 3).$$

At  $x = -1$ ,

$$2 = -4A_2 \implies A_2 = \frac{-1}{2}.$$

At  $x = 3$ ,

$$30 = 4A_1 \implies A_1 = \frac{15}{2}.$$

So,

$$\frac{x^3 + 3}{x^2 - 2x - 3} = x + 2 + \frac{15/2}{x - 3} + \frac{-1/2}{x + 1}.$$

## 0.2 Single Variable Calculus

### 0.2.1 Derivatives and Integrals

#### Derivatives

The derivative of a function  $y = f(x)$ , notated  $f'(x)$ , gives the slope of the tangent line to  $f$  at  $x$ .

**Definition.**

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x + h) - f(x)}{h}.$$

Below are some properties of the derivative. Let  $f$  and  $g$  be functions of  $x$  and  $p$  a scalar.

- **Linearity**

$$(pf \pm g)' = pf' \pm g'$$

- **Product Rule**

$$(fg)' = f'g + fg'$$

- **Quotient Rule**

$$\left(\frac{f}{g}\right)' = \frac{f'g - fg'}{g^2}$$

- **Chain Rule**

$$(f \circ g)' = (f' \circ g) \cdot g'$$

- **Power Rule**

$$\frac{d}{dx} p^x = p x^{p-1}, p \neq 0$$

- **Exponent Rule**

$$\frac{d}{dx} p^x = p^x \ln p, p > 0$$

The Power Rule and Exponent Rule are two cases of the same rule

$$\frac{d}{dx} f^g = g f^{g-1} f' + f^g \ln(f) g'.$$

Using the definition of the derivative and these rules, we can find the derivatives to some common functions.

$$\begin{array}{l|l} \frac{d}{dx} p = 0 & \frac{d}{dx} e^x = e^x \\ \frac{d}{dx} \ln x = \frac{1}{x} & \frac{d}{dx} \sin x = \cos x \\ \frac{d}{dx} \cos x = -\sin x & \frac{d}{dx} \tan x = \sec^2 x \end{array}$$

## Integrals

The definite integral of a function  $f(x)$  from  $x = a$  to  $x = b$  where  $a \leq b$  is the area between  $f(x)$  and the  $x$ -axis bounded by the lines  $x = a$  and  $x = b$  where area above the  $x$ -axis is positive, and area below the  $x$ -axis is negative.

### Definition.

$$\int_a^b f(x) dx = \lim_{h \rightarrow 0} \sum_{n=1}^{\frac{b-a}{h}} f(a + (n-1)h) \cdot h.$$

We also define an indefinite integral, or antiderivative of  $f(x)$ , notated  $F(x)$  where

$$F'(x) = f(x) \implies \int f(x) dx = F(x).$$

Note that there are infinitely many such functions  $F$ , since adding a constant to  $F$  does not affect its derivative. To notate this, we add a constant  $C$  to the indefinite integral. Given an initial condition for  $f$ , we can solve for  $C$ .

Below are some properties of the integral. Let  $f$  and  $g$  be functions of  $x$  and  $p$ ,  $a$ ,  $b$ , and  $c$  where  $a < b < c$ , and  $f$  and  $g$  are continuous on the closed interval  $[a, c]$ .

- **Linearity**

$$\int (pf \pm g)dx = p \int fdx \pm \int gdx$$

- **Flipped Bounds**

$$\int_a^b fdx = - \int_b^a fdx$$

- **Union of Intervals**

$$\int_a^b fdx + \int_b^c fdx = \int_a^c fdx$$

- **Power Rule**

$$\int x^n dx = \frac{x^{n+1}}{n+1} + C, n \neq -1$$

- **U-Substitution**

$$\int (f' \circ g) g' dx = f \circ g + C$$

- **Integration by Parts**

$$\int f' g dx = fg - \int f g' dx$$

- **Fundamental Theorem of Calculus**

$$\frac{d}{dx} \int_a^x f(s) ds = f(x)$$

Using the definition of the integral and the above rules, we can find the indefinite integral of some common functions.

$$\begin{aligned} \int \frac{1}{x} dx &= \ln |x| + C \\ \int \sin x dx &= -\cos x + C \\ \int \cos x dx &= \sin x + C \\ \int \tan x dx &= -\ln |\cos x| + C \end{aligned}$$

### 0.2.2 Taylor Series

A Taylor series as a way of approximating a function about a point  $x = a$  using polynomials. The first approximation just keeps the same value at  $x = a$ , the second approximation keeps the same value and first derivative at  $x = a$ , etc.

**Definition.**

$$f(x) = f(a) + f'(a)(x - a) + \frac{f''(a)}{2!}(x - a)^2 + \dots + \frac{f^{(n)}(a)}{n!}(x - a)^n + \dots$$

If we approximate a function about  $x = 0$ , we call this a Maclaurin series. Below are some common Maclaurin series, and their radii of convergence if applicable.

$$\begin{aligned}e^x &= 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots \\ \sin x &= x - \frac{x^3}{3!} + \frac{x^5}{5!} - \dots \\ \cos x &= 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \dots \\ \frac{1}{1+x} &= 1 - x + x^2 - \dots, \text{ where } |x| < 1 \\ \ln(1+x) &= x - \frac{x^2}{2} + \frac{x^3}{3} - \dots, \text{ where } |x| < 1\end{aligned}$$

#### Euler's Identity

Let's see what happens when we look at the Maclaurin series for  $e^{ix}$ .

$$\begin{aligned}e^{ix} &= 1 + (ix) + \frac{(ix)^2}{2!} + \frac{(ix)^3}{3!} + \frac{(ix)^4}{4!} + \frac{(ix)^5}{5!} \dots \\ &= 1 + ix - \frac{x^2}{2!} - i\frac{x^3}{3!} + \frac{x^4}{4!} + i\frac{x^5}{5!} - \dots \\ &= \left(1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \dots\right) + i\left(x - \frac{x^3}{3!} + \frac{x^5}{5!} - \dots\right).\end{aligned}$$

The two expressions in parenthesis are exactly the Maclaurin series for  $\cos x$  and  $\sin x$ . So,

$$e^{ix} = \cos x + i \sin x.$$

In the case that  $x = \pi$ ,

$$e^{i\pi} = \cos \pi + i \sin \pi = -1 + 0.$$

So,

$$e^{i\pi} + 1 = 0.$$

# Chapter 1

## Vector Spaces

Linear algebra deals with vector spaces and special maps between them. Here we'll define a vector space and provide its most important properties.

### 1.1 Binary Operations

#### 1.1.1 Definition & Notations

**Definition.** For some domain  $D$ , A binary operation is a function  $f : D \times D \rightarrow D$ . That is, it combines two elements of  $D$  to produce another element of  $D$ .

You've already been working with binary operations since elementary school.

**Example.** The following are binary operations with domain  $\mathbb{R}$ .

- Addition (+)
- Multiplication ( $\times$ )

Subtraction ( $-$ ) is also a binary operation on  $\mathbb{R}$ . It is just a special case of addition, since for all  $a, b \in \mathbb{R}$ ,  $a - b = a + (-b)$ , and  $-b \in \mathbb{R}$ .

One needs to specify over which domain a function is a binary operation. Functions can be binary operations over some domains but not others.

**Example.**

- Division ( $\div$ ) is not a binary operation on  $\mathbb{R}$  since  $0 \in \mathbb{R}$ , but dividing by 0 is not defined. However if we consider the domain  $\mathbb{R} \setminus \{0\}$ , then division is a binary operation, since we no longer have to worry about dividing by 0.
- Although we saw that subtraction was a binary operation over  $\mathbb{R}$ , it is not over  $D = \{x \in \mathbb{R} \mid x \geq 0\}$  because  $1, 2 \in D$ , but  $1 - 2 = -1 \notin D$ .

For many binary operations, we tend to abandon function notation in favor of an “infix” notation. For example, we write  $a + b$  or  $a \times b$  rather than  $+(a, b)$  or  $\times(a, b)$ . Sometimes, if the operation is clear from context, we may drop the symbol for the operation entirely and just write the inputs next to each other. For example, if  $a, b \in \mathbb{R}$ , then  $ab$  is understood to mean  $a \times b$ .

### 1.1.2 Properties

A binary operation may have certain useful properties. Let  $\circ$  and  $\square$  be two binary operations with the same domain. Let  $a, b$ , and  $c$  be elements of the domain.

- **Commutative:**  $a \circ b = b \circ a$
- **Associative:**  $(a \circ b) \circ c = a \circ (b \circ c)$
- **Distributive over  $\square$ :**  $a \circ (b \square c) = (a \circ b) \square (a \circ c)$
- **Identity:** There exists  $I$  in the domain such that  $a \circ I = a = I \circ a$
- **Inverse:** There exists  $a^{-1}$  in the domain such that  $a \circ a^{-1} = I = a^{-1} \circ a$

Many of the binary operations you’re already familiar with satisfy some of these properties.

**Example.**

- *Addition over  $\mathbb{R}$  is commutative and associative. Its identity element is 0, and the inverse of  $a$  is  $-a$ .*
- *Multiplication over  $\mathbb{R}$  is commutative and associative. It is distributive over addition. Its identity element is 1. It is not invertable, since 0 doesn’t have an inverse.*
- *Division over  $\mathbb{R} \setminus \{0\}$  is not commutative, since  $1/2 \neq 2/1$ . It is not associative, since  $(1 \div 2) \div 3 = 1/6 \neq 1 \div (2 \div 3) = 3/2$ .*

## 1.2 Euclidean Vectors

### 1.2.1 Definition & Notations

**Definition.** A Euclidean vector is a finite, ordered list of real numbers. Each entry in the vector is called a component. The number of components in a vector is called its dimension. The set of all Euclidean vectors with dimension  $n$  is notated  $\mathbb{R}^n$  and called “Euclidean  $n$ -space”.

Often, vectors are written in square brackets with their components ordered vertically from top to bottom or in angled brackets with their components ordered horizontally from left to right. We tend to symbolically represent some vector by a symbol with an arrow above it. We can represent a certain component of a vector with a subscript.

**Example.** The vector  $\vec{v} = \begin{bmatrix} 4 \\ 5 \end{bmatrix} = \langle 4, 5 \rangle$  is a vector in  $\mathbb{R}^2$ . The components are  $\vec{v}_1 = 4$  and  $\vec{v}_2 = 5$ . Since  $\vec{v}$  can be visualized as a straight arrow in the 2D plane with its tail at the origin and its tip at  $(4, 5)$ , we might also notate the  $x$  and  $y$  components as  $\vec{v}_x = 4$  and  $\vec{v}_y = 5$ .

Figure 1.1: The  $x$  and  $y$  components of a vector  $v$

## 1.2.2 Properties

We can define addition and scalar multiplication of Euclidean vectors.

**Definition.** Let  $\vec{a}, \vec{b} \in \mathbb{R}^n$  and  $c \in \mathbb{R}$  then

1.

$$\vec{a} + \vec{b} = [a_i + b_i \mid i \in \{1, 2, \dots, n\}],$$

2.

$$c \cdot \vec{a} = [c \cdot a_i \mid i \in \{1, 2, \dots, n\}].$$

**Example.** Let  $\vec{u} = \begin{bmatrix} 1 \\ -2 \\ 3 \end{bmatrix}$ ,  $\vec{v} = \begin{bmatrix} -1 \\ 4 \\ 3 \end{bmatrix}$ , and  $\vec{w} = \begin{bmatrix} 4 \\ 2 \\ 6 \end{bmatrix}$ . Find  $(2\vec{u} + \vec{v}) - 3\vec{w}$ .

We find

$$\begin{aligned}
(2\vec{u} + \vec{v}) - 3\vec{w} &= \left( 2 \begin{bmatrix} 1 \\ -2 \\ 3 \end{bmatrix} + \begin{bmatrix} -1 \\ 4 \\ 3 \end{bmatrix} \right) - 3 \begin{bmatrix} 4 \\ 2 \\ 6 \end{bmatrix} \\
&= \left( \begin{bmatrix} 2 \\ -4 \\ 6 \end{bmatrix} + \begin{bmatrix} -1 \\ 4 \\ 3 \end{bmatrix} \right) + \begin{bmatrix} -12 \\ -6 \\ -18 \end{bmatrix} \\
&= \begin{bmatrix} 1 \\ 0 \\ 9 \end{bmatrix} + \begin{bmatrix} -12 \\ -6 \\ -18 \end{bmatrix} \\
&= \begin{bmatrix} -11 \\ -6 \\ -9 \end{bmatrix}.
\end{aligned}$$

Notice that addition of vectors is a binary operation over  $\mathbb{R}^n$ . Also, many of the properties we said binary operations could have are satisfied.

**Theorem.** *The addition of two vectors in  $\mathbb{R}^n$  is commutative and associative. The identity vector is the one containing all 0's. The inverse of any vector  $\vec{v}$  is  $-1 \cdot \vec{v} = -\vec{v}$ . Vector-scalar multiplication<sup>1</sup> is distributive over vector addition.*

## 1.3 Abstract Vector Spaces

### 1.3.1 Definition

**Definition.** *A set  $V$  is a vector space of a field  $F$  (for us,  $\mathbb{R}$  or  $\mathbb{C}$ ) provided that the operations  $\oplus : V \times V \rightarrow V$ , called “addition”, and  $\odot : V \times F \rightarrow V$ , called “scalar multiplication”, are defined and satisfy the following for all  $\vec{u}, \vec{v}, \vec{w} \in V$  and  $a, b \in F$ :*

#### *Addition Properties*

1. **Commutative:**  $\vec{u} \oplus \vec{v} = \vec{v} \oplus \vec{u}$
2. **Associative:**  $\vec{u} \oplus (\vec{v} \oplus \vec{w}) = (\vec{u} \oplus \vec{v}) \oplus \vec{w}$
3. **Additive Identity:** *There exists  $\vec{0} \in V$  such that for all  $\vec{u} \in V$ ,  $\vec{u} \oplus \vec{0} = \vec{u}$ .*
4. **Additive Inverse:** *For each  $\vec{u} \in V$ , there exists  $-\vec{u} \in V$  such that  $\vec{u} \oplus -\vec{u} = \vec{0}$ .*

#### *Multiplication Properties*

1. **Multiplicative Identity:** *There exists  $1 \in F$  such that for all  $\vec{u} \in V$ ,  $1 \odot \vec{u} = \vec{u}$ .*

<sup>1</sup>Vector-scalar multiplication is not a binary operation, but the distributive property still holds

### **Distributive Properties**

1. **Left Distributes Over  $\oplus$ :**  $a \odot (\vec{u} \oplus \vec{v}) = (a \odot \vec{u}) \oplus (a \odot \vec{v})$
2. **Right Distributes Over  $\oplus$ :**  $(\vec{u} \oplus \vec{v}) \odot a = (\vec{u} \odot a) \oplus (\vec{v} \odot a)$
3. **Distributes Over Field Multiplication:**  $(ab) \odot \vec{u} = a \odot (b \odot \vec{u})$

**Example.** Here are a few examples of vector spaces:

- $\mathbb{R}^n$  with operations of vector addition and vector-scalar multiplication over the field  $\mathbb{R}$
- $\mathbb{R}^2$  where
$$\begin{bmatrix} u_1 \\ u_2 \end{bmatrix} \oplus \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} u_1 + v_1 + 1 \\ u_2 + v_2 + 1 \end{bmatrix} \text{ and } a \odot \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \begin{bmatrix} au_1 + 1 \\ au_2 - 1 \end{bmatrix}$$
- All polynomials of degree  $n$  with real coefficients
- $\mathbb{Q}$  over the field  $\mathbb{Q}$
- All real functions that are continuous on  $[0, 1]$

Not all operations for  $\oplus$  and  $\odot$  will result in vector spaces.

**Example.**  $\mathbb{R}$  where

$$a \oplus b = 2a + 2b \text{ and } k \odot a = ka$$

is not a vector space because

$$\begin{aligned} 2 \oplus (3 \oplus 4) &= 2 \oplus 14 = 32, \\ (2 \oplus 3) \oplus 4 &= 10 \oplus 4 = 28, \end{aligned}$$

so  $\oplus$  isn't associative.

### **1.3.2 Properties**

Here are several useful properties of vector spaces. Most of these likely seem intuitively true.

Let  $(V, +, \cdot)$  be a vector space.

**Theorem.** *The additive identity is unique.*

*Proof.* We will show that any two elements of  $V$  that behave like the additive identity must be equal. Suppose  $V$  has two additive identities  $\vec{0}$  and  $\vec{0}'$ . Since both are additive identities,

$$\begin{aligned} \vec{0} &= \vec{0} + \vec{0}' \\ \vec{0}' &= \vec{0} + \vec{0}'. \end{aligned}$$

Since the expressions on the right of each line are equal, the expressions on the left must also be equal. So  $\vec{0} = \vec{0}'$ , as desired. ■

**Theorem.** *The additive inverse of an element is unique.*

*Proof.* Suppose  $\vec{v}$  and  $\vec{v'}$  are both additive inverses of  $\vec{u}$ . Then

$$\begin{aligned}\vec{u} + \vec{v'} &= \vec{0} \text{ and } \vec{u} + \vec{v} = \vec{0} \\ \vec{v} &= \vec{v} + \vec{0} \\ &= \vec{v} + (\vec{u} + \vec{v'}) \\ &= (\vec{v} + \vec{u}) + \vec{v'} \\ &= \vec{0} + \vec{v'} \\ &= \vec{v'},\end{aligned}$$

as desired. ■

**Theorem.** *For all  $\vec{v} \in V$ ,  $0 \cdot \vec{v} = \vec{0}$ .*

*Proof.* Notice that

$$\begin{aligned}0 \cdot \vec{v} &= (0 + 0) \cdot \vec{v} \\ &= 0 \cdot \vec{v} + 0 \cdot \vec{v}.\end{aligned}$$

Let  $\vec{w}$  be the additive inverse of  $0 \cdot \vec{v}$ . Then

$$\begin{aligned}0 \cdot \vec{v} + \vec{w} &= 0 \cdot \vec{v} + 0 \cdot \vec{v} + \vec{w} \\ \vec{0} &= 0 \cdot \vec{v} + \vec{0} \\ \vec{0} &= 0 \cdot \vec{v},\end{aligned}$$

as desired. ■

**Theorem.** *For all  $a \in \mathbb{R}$ ,  $a \cdot \vec{0} = \vec{0}$ .*

*Proof.* Notice that

$$\begin{aligned}a \cdot \vec{0} &= a \cdot (\vec{0} + \vec{0}) \\ &= a \cdot \vec{0} + a \cdot \vec{0}.\end{aligned}$$

Let  $\vec{w}$  be the additive inverse of  $a \cdot \vec{0}$ . Then

$$\begin{aligned}a \cdot \vec{0} + \vec{w} &= a \cdot \vec{0} + a \cdot \vec{0} + \vec{w} \\ \vec{0} &= a \cdot \vec{0} + \vec{0} \\ \vec{0} &= a \cdot \vec{0},\end{aligned}$$

as desired. ■

**Theorem.** For all  $\vec{v} \in V$ ,  $-1 \cdot \vec{v} = -\vec{v}$ .

*Proof.* Notice,

$$\begin{aligned}
 -1 \cdot \vec{v} &= -1 \cdot \vec{v} + \vec{0} \\
 &= -1 \cdot \vec{v} + (\vec{v} - \vec{v}) \\
 &= (-1 \cdot \vec{v} + \vec{v}) - \vec{v} \\
 &= (-1 + 1) \vec{v} - \vec{v} \\
 &= \vec{0} - \vec{v} \\
 &= -\vec{v},
 \end{aligned}$$

as desired. ■

### 1.3.3 Subspaces

**Definition.** A non-empty subset  $U$  of a vector space  $V$  is a subspace of  $V$  if  $U$  is a vector space with the operations inherited from  $V$ .

**Example.** Here are a few examples of subspaces:

- The set of vectors  $\left\{ \begin{bmatrix} x \\ y \\ 0 \end{bmatrix} \mid x, y \in \mathbb{R} \right\}$  is a subspace of  $\mathbb{R}^3$ .
- The set of real-valued functions  $\{f \in \mathbb{R}^{[0,1]} \mid \int_0^1 f(x)dx = 0\}$  is a subspace of all real-valued functions that are integrable over  $[0, 1]$ ,  $\mathbb{R}^{[0,1]}$ .
- The set of functions  $\{f : [0, 1] \rightarrow \mathbb{R} \mid f'(1/2) = 0\}$  is a subspace of  $\mathbb{R}^{[0,1]}$ .

**Example.** Here are a few non-examples of subspaces:

- The set of vectors  $W = \left\{ \begin{bmatrix} x \\ y \\ z \end{bmatrix} \mid x, y, z \in \mathbb{R}, 2x + y - z = -4 \right\}$  is not a subspace of  $\mathbb{R}^3$  because  $\vec{0} \notin W$ , meaning there is no additive identity.
- The set of real-valued functions  $\{f \in \mathbb{R}^{[0,1]} \mid \int_0^1 f(x)dx = 1\}$  is not a subspace of  $\mathbb{R}^{[0,1]}$  because it is not closed under addition.
- The set of functions  $\{f : [0, 1] \rightarrow \mathbb{R} \mid f'(1/2) = 1\}$  is not a subspace of  $\mathbb{R}^{[0,1]}$  because it is not closed under scalar multiplication.

It would be tedious to recheck all the vector space conditions when seeing if a set is a subspace. Thankfully, we have an easier subspace test

**Theorem.** *Let  $U$  be a non-empty subset of a vector space  $V$ .  $U$  is a subspace of  $V$  if and only if  $U$  is closed under addition and scalar multiplication.*

*Proof.* Assume that  $U$  is closed under addition and scalar multiplication. Since  $U \subseteq V$ , the addition properties of commutativity and associativity hold, the multiplicative identity is in  $U$ , and the distributive properties all hold. Thus, all that remains to check is whether the additive inverse exists, and whether each element of  $U$  has an additive inverse.

Let  $\vec{u} \in U$ . Since  $U \subset V$  and  $V$  is a vector space, there exists  $-\vec{u} \in V$ . By previous result, we know that  $-\vec{u} = -1 \cdot \vec{u}$ . Since  $U$  is closed under scalar multiplication,  $-\vec{u} \in U$ . Further, since  $\vec{u} + -\vec{u} = \vec{0}$ , and  $U$  is closed under addition,  $\vec{0} \in U$ . ■

# Chapter 2

## Finite Dimensional Vector Spaces

If you've worked with vectors in  $\mathbb{R}^2$  before, you might have noticed that we can write any vector using only two vectors and scalar multiplication: one to represent the  $x$  component and another to represent the  $y$  component.

$$\begin{bmatrix} v_x \\ v_y \end{bmatrix} = v_x \begin{bmatrix} 1 \\ 0 \end{bmatrix} + v_y \begin{bmatrix} 0 \\ 1 \end{bmatrix}.$$

Although  $\langle 1, 0 \rangle$  and  $\langle 0, 1 \rangle$  are probably the most convenient vectors to use to break up any vector, other representations are possible.

$$\begin{bmatrix} v_x \\ v_y \end{bmatrix} = \frac{v_y + v_x}{2} \begin{bmatrix} 1 \\ 1 \end{bmatrix} + \frac{v_y - v_x}{2} \begin{bmatrix} -1 \\ 1 \end{bmatrix}.$$

We'll formalize for vector spaces like  $\mathbb{R}^2$  when one can or can't write a vectors in this way, and how many vectors are needed to do so.

### 2.1 Linear Span

#### 2.1.1 Definition

**Definition.** Let  $S = \{\vec{v}_1, \vec{v}_2, \dots, \vec{v}_n\}$  be a set of  $n$  vectors from a vector space  $V$ . A linear combination of vectors from  $S$  is any vector  $\vec{v}$  such that

$$\vec{v} = a_1 \vec{v}_1 + a_2 \vec{v}_2 + \dots + a_n \vec{v}_n = \sum_{i=1}^n a_i \vec{v}_i,$$

where each  $a_i$  is from the field associated with  $V$ .

From above we see that any vectors in  $\mathbb{R}^2$  can be written as a linear combination of the vectors  $\langle 1, 0 \rangle$  and  $\langle 0, 1 \rangle$ .

**Definition.** Let  $S = \{\vec{v}_1, \vec{v}_2, \dots, \vec{v}_n\}$  be a set of  $n$  vectors from a vector space  $V$ . The span of  $S$ , written  $\text{span } S$ , is the set of all vectors from  $V$  that can be written as a linear combination of vectors from  $S$ .

**Example.**

$$\begin{bmatrix} 1 \\ 3 \\ 5 \end{bmatrix} \in \text{span} \left\{ \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} \right\} = \mathbb{R}^3; 2x^2 - 3x + 3 \in \text{span}\{2, 1 - x, 1 + x^2\}.$$

**Example.**

$$\text{span} \left\{ \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix}, \begin{bmatrix} 2 \\ 0 \\ 1 \end{bmatrix} \right\} = \left\{ \begin{bmatrix} x \\ y \\ z \end{bmatrix} \in \mathbb{R}^3 \mid 2x + 5y - 4z = 0 \right\}$$

### 2.1.2 Span Is a Subspace

**Theorem.** Let  $S = \{\vec{v}_1, \vec{v}_2, \dots, \vec{v}_n\}$  be a set of  $n$  vectors from a vector space  $V$ . Then  $\text{span } S$  is the smallest subspace of  $V$  containing all vectors in  $S$ .

*Proof.* Since  $S \subseteq V$ , and  $V$  is closed under addition and scalar multiplication by virtue of being a vector space,  $\text{span } S \subseteq V$ .

First we'll show closure under addition. Let  $\vec{a}, \vec{b} \in \text{span } S$ . Then

$$\begin{aligned} \vec{a} &= a_1 \vec{v}_1 + a_2 \vec{v}_2 + \dots + a_n \vec{v}_n \\ \vec{b} &= b_1 \vec{v}_1 + b_2 \vec{v}_2 + \dots + b_n \vec{v}_n. \end{aligned}$$

So,

$$\vec{a} + \vec{b} = (a_1 + b_1) \vec{v}_1 + (a_2 + b_2) \vec{v}_2 + \dots + (a_n + b_n) \vec{v}_n.$$

Since each  $(a_i + b_i)$  is in the associated field, we see that we can write  $\vec{a} + \vec{b}$  as a linear combination of vectors from  $S$ . Thus,  $\text{span } S$  is closed under addition.

Now we'll show scalar multiplication. Let  $\vec{a} \in \text{span } S$  and  $k$  be an element from the associated field.

$$k\vec{a} = (ka_1) \vec{v}_1 + (ka_2) \vec{v}_2 + \dots + (ka_n) \vec{v}_n.$$

Since each  $ka_i$  is in the associated field, we see that we can write  $k\vec{a}$  as a linear combination of vectors from  $S$ . Thus,  $\text{span } S$  is closed under multiplication.

Now that we've shown  $\text{span } S$  is a subspace of  $V$ , we'll show it's the smallest one containing all elements from  $S$ . Suppose  $U$  is a subspace of  $V$  containing all elements from  $S$ . Let  $\vec{a} \in \text{span } S$ . Since  $U$  contains all vectors from  $S$  and is a subspace,  $\vec{a} \in U$ . Thus,  $\text{span } S \subseteq U$ . ■

### 2.1.3 Finite & Infinite Dimension

**Definition.** Let  $S = \{\vec{v}_1, \vec{v}_2, \dots, \vec{v}_n\}$  be a set of  $n$  vectors. If  $\text{span } S = V$ , a vector space, then we say

- $S$  spans  $V$
- $S$  is a spanning set of  $V$

**Definition.** A vector space is finite dimensional if it has a finite spanning set. Otherwise, it is infinite dimensional.

**Example.** We see from the previous examples that

$$\text{span} \left\{ \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} \right\} = \mathbb{R}^3.$$

Thus,  $\mathbb{R}^3$  is a finite dimensional vector space.

**Example.** The set of all polynomials with real coefficients is infinite dimensional because any finite set could only represent polynomials up to some finite degree.

## 2.2 Linear Independence

### 2.2.1 Definition

**Definition.** Let  $S = \{\vec{v}_1, \vec{v}_2, \dots, \vec{v}_n\}$  be a set of  $n$  vectors from a vector space  $V$ . The set  $S$  is said to be linearly independent if the only solution to

$$a_1 \vec{v}_1 + a_2 \vec{v}_2 + \dots + a_n \vec{v}_n = \vec{0}$$

is  $a_1 = a_2 = \dots = a_n = 0$ . Otherwise,  $S$  is said to be linearly dependent.

In other words, if we can write a vector from  $S$  as a linear combination of the other vectors from  $S$ , then  $S$  is linearly dependent. Linearly independent sets don't have such redundancies. Equivalently,  $S$  is linearly independent if and only if every element of  $\text{span } S$  can be written in one and only way as a linear combination of elements from  $S$ . If there were two unique representations, we could subtract them to get a non-zero solution to our equation. Notice too that this equation itself is asking for a representation of  $\vec{0}$  other than all coefficients set to 0.

**Example.** Determine whether or not the following sets are linearly independent or dependent

1.

$$\{1, x, x^2, 2x^2 - x\}$$

2.

$$\left\{ \begin{bmatrix} 1 \\ 0 \\ 1 \\ 2 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \\ 1 \\ 2 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 3 \end{bmatrix} \right\}$$

1. This set is not linearly independent because

$$0(1) + -1(x) + 2(x^2) + 1(2x^2 - x) = 0.$$

2. Let the three vectors be called  $\vec{v}_1$ ,  $\vec{v}_2$ , and  $\vec{v}_3$  respectively. Let's consider solutions of the equation

$$a\vec{v}_1 + b\vec{v}_2 + c\vec{v}_3 = \vec{0}.$$

Since  $\vec{v}_1$  and  $\vec{v}_3$ , both have 1 in their first component,  $a + c = 0$ . Similarly, looking at  $\vec{v}_2$  and  $\vec{v}_3$ , we find that  $b + c = 0$ . Thus,  $a = b$  and  $c = -a$ . So, our equation becomes

$$a\vec{v}_1 + a\vec{v}_2 - a\vec{v}_3 = \vec{0}$$

$$a(\vec{v}_1 + \vec{v}_2 - \vec{v}_3) = \vec{0}$$

$$a \begin{bmatrix} 0 \\ 0 \\ 1 \\ 1 \end{bmatrix} = \vec{0}$$

$$a = 0.$$

We see that the only solution is  $a = b = c = 0$ , so the set is linearly independent.

## 2.2.2 Properties

**Theorem.** Let  $V$  be a vector space. Let  $S \subseteq T \subseteq V$ . If  $T$  is linearly independent, then so is  $S$ .

Notice that since all sets that are not linearly independent are linearly dependent, the contrapositive would be "If  $S$  is linearly dependent, then so is  $T$ ".

**Theorem.** Let  $S = \{\vec{v}_1, \vec{v}_2, \dots, \vec{v}_n\}$  be a set of  $n$  vectors from a vector space  $V$ . The set  $S$  is linearly dependent if and only if there exists some  $\vec{v}_j \in S$  such that  $\vec{v}_j \in \text{span}(S \setminus \{\vec{v}_j\})$ . If this is the case, then  $\text{span } S = \text{span}(S \setminus \{\vec{v}_j\})$ .

**Theorem.** Let  $V$  be finite dimensional vector space. The size of any linearly independent set in  $V$  is at most the size of a spanning set of  $V$ .

*Proof.* Suppose  $U = \{\vec{u}_1, \dots, \vec{u}_m\}$  is linearly independent in  $V$ . Suppose that  $W = \{\vec{w}_1, \dots, \vec{w}_n\}$  spans  $V$ .

Initialize  $B = W$ , then add  $\vec{u}_1$  to  $B$ . Since  $W$  spans  $V$ , adding  $\vec{u}_1$  to  $B$  ensures that  $B$  is linearly dependent. By previous result, we can remove some vector other than  $\vec{u}_1$  from  $B$  while still ensuring that  $B$  spans  $V$ . Remove one such vector.

Continue in this way, adding each vector from  $U$  to  $B$  one at a time. By previous result, we know we can remove one vector from  $B$  while still being sure it will span  $S$ . Since all the vectors from  $U$  are linearly independent, we can be sure that this vector will be from  $W$ .

After doing this for all vectors in  $U$ , we see that at each step we were sure there was a vector from  $W$  to remove. Thus, there must at least as many elements of  $W$  than of  $U$ . ■

**Theorem.** Every subspace of a finite dimensional vector space is finite dimensional.

*Proof.* Suppose  $U$  is a subspace of  $V$  where  $V$  is finite dimensional. If  $U = \{\vec{0}\}$ , then we are done; otherwise, select a vector  $\vec{v}_1 \in U$ . Continue in the following way: If  $U = \text{span}\{\vec{v}_1, \vec{v}_2, \dots, \vec{v}_{j-1}\}$  then we are done; otherwise, select a vector  $\vec{v}_j$  not in this span. Since no vector we selected is in the span of the previous, the set of selected vectors is independent. By previous result, the set of selected vectors cannot be longer than a spanning set of  $V$ , so we know this process terminates. Thus, the set of selected vectors spans  $U$  and is finite, meaning that  $U$  is finite dimensional. ■

## 2.3 Bases

### 2.3.1 Definition

**Definition.** Let  $V$  be a vector space. A non-empty set  $S$  of vectors from  $V$  is a basis for  $V$  if

1.  $S$  is a spanning set of  $V$ .
2.  $S$  is linearly independent.

**Example.** We saw before that the set  $\{\langle 1, 0, 0 \rangle, \langle 0, 1, 0 \rangle, \langle 0, 0, 1 \rangle\}$  is linearly independent and spans  $\mathbb{R}^3$ . Thus, it is a basis for  $\mathbb{R}^3$ . This is called the “standard basis” for  $\mathbb{R}^3$ , and the same pattern holds for  $\mathbb{R}^n$ .

**Example.** The set  $\{1, x, x^2, \dots\}$  is a basis for the infinite dimensional vector space of polynomials with real coefficients.

**Example.** Although  $\{\langle 1, 0, 1, 2 \rangle, \langle 0, 1, 1, 2 \rangle, \langle 1, 1, 1, 3 \rangle\}$  is linearly independent, it does not span  $\mathbb{R}^4$  because  $\langle 1, 1, 1, 1 \rangle$  is in  $\mathbb{R}^4$  but is not in the span of these three vectors.

### 2.3.2 Properties

A basis extends the idea of linear independence from just considering the zero vector to all vectors in a vector space.

**Theorem.** A set of vectors  $\{\vec{v}_1, \vec{v}_2, \dots, \vec{v}_n\}$  from a vector space  $V$  is a basis for  $V$  if and only every vector  $\vec{v} \in V$  can be uniquely written in the form

$$\vec{v} = a_1 \vec{v}_1 + a_2 \vec{v}_2 + \dots + a_n \vec{v}_n,$$

where  $a_1, a_2, \dots, a_n$  are from the field associated with  $V$ .

**Theorem.** Every spanning set of a vector space  $V$  can be made into a basis for  $V$  by removing some elements.

*Proof.* To make a spanning set into a basis, we need to remove vectors from the set to make it linearly independent, while still maintaining a spanning set of  $V$ . Start by removing all zero vectors from the set. Next, continue by removing vector  $\vec{v}_j$  from the set if it's in  $\text{span}\{\vec{v}_1, \dots, \vec{v}_{j-1}\}$ . The resulting set is linearly independent because all vectors are not in the span of the previous. The resulting set also still spans  $V$  because we only removed vectors that were already in the span of previous vectors. Thus, the resulting set is a basis for  $V$ . ■

**Corollary.** *Every finite dimensional vector space has a basis.*

*Proof.* By definition, a finite dimensional vector space has a finite spanning set. So, we simply apply the process described previously to make a basis from the spanning set. ■

Just like we could remove vectors from a spanning set to form a basis, we can also add vectors to a linearly independent set.

**Theorem.** *Every linearly independent set of vectors from a finite dimensional vector space  $V$  can be extended to make a basis for  $V$ .*

*Proof.* Let  $U = \{\vec{u}_1, \vec{u}_2, \dots, \vec{u}_m\}$  be a linearly independent set of vectors from  $V$ . Let  $W = \{\vec{w}_1, \vec{w}_2, \dots, \vec{w}_n\}$  be a basis of  $V$ . Then the set  $U \cup W = \{\vec{u}_1, \dots, \vec{u}_m, \vec{w}_1, \dots, \vec{w}_n\}$  certainly spans  $V$ . When we apply the procedure to turn this spanning set into a basis for  $V$ , none of the vectors from  $U$  get removed, since they are linearly independent. Thus, our resulting basis is an extension of  $U$  with some vectors from  $W$ , as desired. ■

## 2.4 Dimension

We saw that a basis is both a linearly independent and spanning set. We shall see that we can't have two bases for the same vector space of different sizes. Thus, the length of a basis for a vector space is a special number, which we'll call "dimension".

### 2.4.1 Definition

**Theorem.** *Any two bases of the same finite dimensional vector space  $V$  have the same size.*

*Proof.* Let  $B_1$  and  $B_2$  be two bases for  $V$ . Since  $B_1$  is linearly independent in  $V$ , and  $B_2$  spans  $V$ ,

$$|B_1| \leq |B_2|,$$

by previous result. Similarly, since  $B_2$  is linearly independent in  $V$ , and  $B_1$  spans  $V$ ,

$$|B_1| \leq |B_2|,$$

by previous result. Thus,

$$|B_1| = |B_2|,$$

as desired. ■

**Definition.** *Let  $V$  be a finite dimensional vector space. The dimension of  $V$ , denoted  $\dim V$ , is the size of any basis for  $V$ .*

**Example.** *Here are the dimension of some vector spaces:*

- $\dim \mathbb{R}^n = n$ , since the standard basis has  $n$  elements.
- $\mathcal{P}_m$ , the set of a polynomials with real coefficients of degree at most  $m$ , has dimension  $m + 1$  since  $\{1, x, x^2, \dots, x^m\}$  is a basis.
- The set of all  $n \times m$  matrices with real coefficients has dimension  $nm$  (imagine "unwrapping" the matrix to look like a vector in  $\mathbb{R}^{nm}$ ).

### 2.4.2 Properties

Our results about the length of linearly independent sets and subspaces extend to dimension.

**Theorem.** *If  $U$  is a subspace of a finite dimensional vector space  $V$ , then  $\dim U \leq \dim V$ .*

*Proof.* A basis for  $U$  is linearly independent in  $V$ , and a basis for  $V$  spans  $V$ . So, applying a previous result and the definition of dimension,  $\dim U \leq \dim V$ . ■

Any linearly independent set of vectors with size equal to the dimension is a basis.

**Theorem.** *Let  $V$  be a finite dimensional vector space. Then every linearly independent set of vectors from  $V$  with size  $\dim V$  is a basis for  $V$ .*

*Proof.* Let  $\dim V = n$ , and suppose  $U = \{\vec{v}_1, \vec{v}_2, \dots, \vec{v}_n\}$  is linearly independent in  $V$ . We know by previous result that we can extend  $U$  to form a basis. This basis must have  $n$  elements. Thus, the extension is trivial and adds no vectors, meaning  $U$  is a basis for  $V$ . ■

Similarly, any spanning set of vectors with size equal to the dimension is a basis.

**Theorem.** *Let  $V$  be a finite dimensional vector space. Then every spanning set of vectors from  $V$  with size  $\dim V$  is a basis for  $V$ .*

*Proof.* Let  $\dim V = n$ , and suppose  $S = \{\vec{v}_1, \dots, \vec{v}_n\}$  is a spanning set in  $V$ . We know by previous result that we can remove vectors from  $S$  to form a basis. Thus basis must have  $n$  elements. Thus, the removal is trivial and removes no vectors, meaning  $S$  is a basis for  $V$ . ■

**Example.** *Show that  $\{\langle 1, 1 \rangle, \langle -1, 1 \rangle\}$  is a basis for  $\mathbb{R}^2$ .*

We showed previously that any vector from  $\mathbb{R}^2$  can be written as a linear combination of these vectors. Thus, the set is spanning. Since  $\dim \mathbb{R}^2 = 2$ , and our spanning set has 2 elements, it must be a basis.

# Chapter 3

## Linear Maps

Now that we have an understanding of finite dimensional vector spaces, we can investigate the mappings between vector spaces that preserve these properties.

### 3.1 Linear Transformations

#### 3.1.1 Definition

**Definition.** A linear map (linear transformation) from a vector space  $V$  to a vector space  $W$  is a function  $T : V \rightarrow W$  that preserves the linearity properties of  $V$  and  $W$ . That is, for all  $\vec{u}, \vec{v} \in V$  and  $k \in F$ , where  $F$  is the field associated with  $V$  and  $W$ ,

$$\begin{aligned}T(\vec{u} + \vec{v}) &= T(\vec{u}) + T(\vec{v}) \\T(k\vec{u}) &= kT(\vec{u}).\end{aligned}$$

Often, we'll drop the parentheses and write  $T\vec{u}$ .

**Example.** Show that  $T : \mathbb{R}^2 \rightarrow \mathbb{R}^2$  defined by  $T(\langle x, y \rangle) = \langle x + y, x - y \rangle$  is a linear transformation.

We'll show each of the properties hold. For the first property:

$$\begin{aligned}T(\langle x_1, y_1 \rangle + \langle x_2, y_2 \rangle) &= T(\langle x_1 + x_2, y_1 + y_2 \rangle) \\&= \langle x_1 + x_2 + y_1 + y_2, x_1 - x_2 + y_1 - y_2 \rangle \\&= \langle x_1 + y_1, x_1 - y_1 \rangle + \langle x_2 + y_2, x_2 - y_2 \rangle \\&= T(\langle x_1, y_1 \rangle) + T(\langle x_2, y_2 \rangle).\end{aligned}$$

For the second property:

$$\begin{aligned}T(k\langle x, y \rangle) &= T(\langle kx, ky \rangle) \\&= \langle kx + ky, kx - ky \rangle \\&= k\langle x + y, x - y \rangle \\&= kT(\langle x, y \rangle).\end{aligned}$$

## Set of All Linear Maps

**Definition.** The set of all linear maps from  $V$  to  $W$  is denoted  $\mathcal{L}(V, W)$ .

There are two important elements of this set, which have special notations.

- **Zero** This is the transformation that sends all elements to  $W$ 's zero vector. It is notated as  $0$ , or as  $\mathbf{0}$ .
- **Identity** This map exists when  $V = W$  and sends all elements to themselves. It is notated as  $I$ , or as  $\mathbf{1}$ .

### 3.1.2 Properties

**Theorem.** A linear transformation  $T : V \rightarrow W$  is uniquely determined by how it transforms the vectors in a basis for  $V$ .

*Proof Sketch.* Let  $B = \{\vec{v}_1, \vec{v}_2, \dots, \vec{v}_n\}$  be a basis for  $V$ . Let  $\vec{v} \in V$ . Since  $B$  is a basis,  $\vec{v}$  has a unique representation as a linear combination of vectors from  $B$ . So,

$$\begin{aligned}\vec{v} &= a_1 \vec{v}_1 + a_2 \vec{v}_2 + \dots + a_n \vec{v}_n \\ T\vec{v} &= T(a_1 \vec{v}_1 + a_2 \vec{v}_2 + \dots + a_n \vec{v}_n) \\ &= T(a_1 \vec{v}_1) + T(a_2 \vec{v}_2) + \dots + T(a_n \vec{v}_n) \\ &= a_1 T\vec{v}_1 + a_2 T\vec{v}_2 + \dots + a_n T\vec{v}_n.\end{aligned}$$

■

**Corollary.** For any linear transformation  $T : V \rightarrow W$ ,  $T\vec{0} = \vec{0}$ .

**Theorem.** Let  $B = \{\vec{v}_1, \vec{v}_2, \dots, \vec{v}_n\}$  be a basis for  $V$  and  $\vec{w}_1, \dots, \vec{w}_n \in W$ . Then there exists a unique linear map  $T : V \rightarrow W$  such that

$$T\vec{v}_j = \vec{w}_j$$

for  $j = 1, 2, \dots, n$ . In particular, the transformation is

$$T(a_1 \vec{v}_1 + \dots + a_n \vec{v}_n) = a_1 \vec{w}_1 + \dots + a_n \vec{w}_n.$$

## Operations on Set of Linear Transformations

We can define addition and scalar multiplication on  $\mathcal{L}(V, W)$  and show that we in fact have a vector space.

**Definition.** Let  $S, T \in \mathcal{L}(V, W)$  and  $k$  be a scalar from the associated field. Then for all  $\vec{v} \in V$ ,

$$(S + T)(\vec{v}) = S\vec{v} + T\vec{v}$$

and

$$(kT)(\vec{v}) = k(T\vec{v}).$$

**Theorem.** *The set  $\mathcal{L}(V, W)$  with the operations defined above is a vector space.*

We can also define the multiplication of two elements as function composition.

**Definition.** *Let  $S \in \mathcal{L}(V, U)$  and  $T \in \mathcal{L}(U, W)$ . Then for all  $\vec{v} \in V$ ,*

$$(ST)(\vec{v}) = S(T\vec{v}).$$

This is normally notated  $ST\vec{v}$ . Notice that even if the domains and codomains allow  $TS\vec{v}$  to be defined, multiplication of linear transformations is not in general commutative:  $ST\vec{v} \neq TS\vec{v}$ .

There are however some properties of multiplication that hold

**Theorem.** *The following properties of multiplication of linear transformations holds (assuming the domains and codomains allow the operations to be defined):*

- **Associativity:**  $(T_1 T_2) T_3 = T_1 (T_2 T_3)$ .
- **Identity:**  $TI = IT = T$ .
- **Left & Right Distributive:**  $(T_1 + T_2) T_3 = T_1 T_3 + T_2 T_3$  and  $T_1 (T_2 + T_3) = T_1 T_2 + T_1 T_3$ .
