Chapter 0

Background & Review

Everything mentioned in this chapter should already be familiar to you from other math classes. These topics span two main areas: algebra/pre-calculus and single variable calculus. Ideas from algebra and pre-calculus will be used either implicitly or with only a passing reference. Topics from single variable calculus will mostly be used in setting up problems.

If you are unfamiliar with anything mentioned, you can use many of the great online resources like Khan Academy, to familiarize yourself before moving forward.

0.1 Algebra and Pre-Calculus

0.1.1 Sets

Definition. A set A is a collection of distinct elements. Those elements can be anything, like numbers, functions, and even other sets.

We can define a set by giving its elements, like $A = \{-2, 5, 3\}$ or by describing its properties, like $A = \{x \mid x > 0\}$ where the vertical bar means “such that”. If an object x is a member of the set A , we write $x \in A$.

A set A is called a subset of a set B if every element of A is also an element of B . We can write this as $A \subseteq B$. For example, $\{7, 10, 16\} \subseteq \{5, 6, 7, 9, 10, 11, 16\}$. Note that this relation can be strict if there exists at least one element in B that is not also an element of A . Some common sets and their informal definitions are given below:

Set Name	Symbol	Informal Definition
Natural numbers	\mathbb{N}	$\{1, 2, 3, \dots\}$
Integers	\mathbb{Z}	$\{\dots, -3, -2, -1, 0, 1, 2, 3, \dots\}$
Rational numbers	\mathbb{Q}	$\{\frac{m}{n} \mid m, n \in \mathbb{Z} \text{ and } n \neq 0\}$
Real numbers	\mathbb{R}	Any number on the number line ¹

This means that $\mathbb{N} \subset \mathbb{Z} \subset \mathbb{Q} \subset \mathbb{R}$.

There are several common operations that can be performed on sets. The union $A \cup B$ of two sets A and B is the set of all elements that are elements of A or of B . Similarly, the intersection $A \cap B$ of two sets A and B is the set of all elements that are also elements of both A and B .

Example. If $A = \{\sqrt{2}, 2, 5, 8\}$ and $B = \{-9, 8, 2.3\}$, what are $A \cup B$ and $A \cap B$?

To find the union, we combine the sets, making sure to include any repeated element only once:

$$A \cup B = \{-9, \sqrt{2}, 2, 2.3, 5, 8\}.$$

Then, since the only element both sets share is 8, we also have

$$A \cap B = \{8\}.$$

0.1.2 Intervals

Definition. We call a subset I of \mathbb{R} an interval if, for any $a, b \in I$ and $x \in \mathbb{R}$ such that $a \leq x \leq b$, then $x \in I$.

We can write an interval more simply using the notation $[a, b]$, which is equivalent to $\{x \in \mathbb{R} \mid a \leq x \leq b\}$. This is called a closed interval, and to make the inequalities strict, we can also define an open interval by using parantheses instead of square brackets.

In addition, we can mix the two to create half-open intervals, where one inequality is strict and the other isn't. For instance, $(2, 5]$ refers to the set $\{x \in \mathbb{R} \mid x < 2 \leq 5\}$. Finally, if the interval is unbounded in either direction, we use the notations $-\infty$ and ∞ to indicate that there is no minimum or maximum, respectively.

Example. Is $8 \in (-\infty, 4) \cup [8, 100)$?

Since $8 \leq 8 < 100$ is a true statement, $8 \in [8, 100)$. Since we are taking the union with another set, all of the members of the right interval will also be members of the union of intervals. Therefore, the statement is true.

0.1.3 Functions

Definition. A function f is a rule between a pair of sets, denoted $f : D \rightarrow C$, that assigns values from the first set, the domain D , to the second set, the codomain C .

We call the subset of the codomain C that constitutes all values f can actually attain the range $R \subseteq C$. Note that when we draw a graph of a function, all we are doing is drawing all ordered pairs $\{(x, f(x)) \mid x \in D\}$.

Example. Find the domain of the following function:

$$f(x) = \frac{1}{(1-x)\sqrt{5-x^2}}$$

We know that $\frac{n}{0}$ is undefined for all $n \in \mathbb{R}$ and \sqrt{x} is only defined for $x \geq 0$. The first condition applies to the first term in the denominator and both conditions apply to the second, giving us

$$(1-x) \neq 0 \text{ and } 5-x^2 > 0$$

The first condition implies $x \neq 1$ while the second implies $|x| < \sqrt{5}$. Putting these together, we find that the domain is

$$\{x \mid x \neq 1, |x| < \sqrt{5}\} \text{ or } (-\sqrt{5}, 1) \cup (1, \sqrt{5})$$

We can also compose two functions, such that the output of one function is the input of another:

$$(f \circ g)(x) = f(g(x)).$$

Definition. A function g is called an inverse function of f if $f(g(x)) = x$ for all x in the domain of g and $g(f(x)) = x$ for all x in the domain of f . We write this as $g = f^{-1}$.

One common algorithm for finding an inverse function is to set $y = f(x)$, substitute all x 's for y 's, and then solve for y .

Example. Find the inverse function of

$$f(x) = \frac{5x+2}{4x-3}.$$

We first make the substitutions to set up the algorithm:

$$y = \frac{5x+2}{4x-3} \text{ followed by } x = \frac{5y+2}{4y-3}$$

After multiplying both sides by the denominator and simplifying, we have

$$\implies 4xy - 3x = -5y - 2 \implies y = f^{-1}(x) = \frac{3x-2}{4x+5}.$$

We say that a function f is even if it satisfies $f(-x) = f(x)$ for all $x \in D$. Likewise, we say that a function f is odd if it satisfies $f(-x) = -f(x)$ for all $x \in D$. Geometrically, we can see that the graph of an even function is symmetric with respect to the y -axis, while the graph of an odd function is symmetric with respect to the origin.

Example. Is $f(x) = 2x - x^2$ even, odd, or neither?

$$f(-x) = 2(-x) - (-x)^2 = -2x - x^2$$

Since $f(-x) \neq f(x)$ and $f(-x) \neq -f(x)$, the function is neither even nor odd.

0.1.4 Complex Numbers

Definition. i is called the imaginary unit. It's defined by $i^2 = -1$.

The set of complex numbers (\mathbb{C}) is an extension of the real numbers. Complex numbers have the form $z = \alpha + \beta i$, where α and β are real numbers. The α part of z is called the real part, so $\Re(z) = \alpha$. The β part of z is called the imaginary part, so $\Im(z) = \beta i$.

Often, complex numbers are visualized as points or vectors in a 2D plane, called the complex plane, where α is the x-component, and β is the y-component. Thinking of complex numbers like points helps us define the magnitude of complex numbers and compare them. Since a point (x, y) has a distance $\sqrt{x^2 + y^2}$ from the origin, we can say the magnitude of z , $|z|$ is $\sqrt{\alpha^2 + \beta^2}$. Thinking of complex numbers like vectors helps us understand adding two complex numbers, since you just add the components like vectors.

A common operation on complex numbers is the complex conjugate. The complex conjugate of $z = \alpha + \beta i$ is $\bar{z} = \alpha - \beta i$. z and \bar{z} are called a conjugate pair.

Conjugate pairs have the following properties. Let $z, w \in \mathbb{C}$ and $n \in \mathbb{Z}$.

$$\begin{aligned}\overline{z \pm w} &= \bar{z} \pm \bar{w} \\ \overline{zw} &= \bar{z} \cdot \bar{w} \\ \bar{\bar{z}} &= z \Leftrightarrow z \in \mathbb{R} \\ z\bar{z} &= |z|^2 = |\bar{z}|^2 \\ \overline{\bar{z}} &= z \\ \bar{z}^n &= \overline{z^n} \\ z^{-1} &= \frac{\bar{z}}{|z|^2}\end{aligned}$$

0.1.5 Factoring Polynomials

We want to break up a polynomial like $f(x) = a_0 + a_1x^1 + \dots + a_nx^n$ into linear factors so that $f(x) = c(x - b_1) \cdot \dots \cdot (x - b_n)$. This form makes it simple to see that the roots of f , solutions to $f(x) = 0$, are $x = b_1 \dots b_n$.

For quadratics, $f(x) = ax^2 + bx + c$, there exists a simple formula that will give us both roots, the quadratic formula

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.$$

We can see that when $b^2 - 4ac < 0$, like for $f(x) = x^2 + 5x + 10$, we will get complex roots $\alpha \pm \beta i$. For any polynomial, these roots come in pairs, so if $\alpha + \beta i$ is a root, then so is $\alpha - \beta i$. This means that every conjugate pair $\alpha \pm \beta i$ has a quadratic equation with those roots. Sometimes we will not

factor quadratics with complex roots into linear terms.

Although there do exist explicit formulas for finding roots for cubic (degree 3) and quartic (degree 4) equations, they are too long and not useful enough to memorize. When working by hand, we instead use other tricks to find roots.

There are a few useful tricks that can help. If the polynomial doesn't have a constant term, then 0 is a root. If all the coefficients sum to 0, then 1 is a root. For certain polynomials with an even number of terms, like all cubics of the form $ax^3 + bx^2 + cx + d$ we can factor out a term from the first two and last two terms to get $x^2(ax + b) + c(ax + b) = (ax + b)(x^2 + c)$. For other polynomials, we might just try guessing and checking values. However, we need a more efficient way that works in general.

Since we are looking to find linear factors $f(x) = (x - b_1) \cdot \dots \cdot (x - b_n)$, we can see that the constant term in the polynomial is the product of the roots $b_1 \cdot \dots \cdot b_n$. In fact, since the coefficients of polynomials are completely determined by the roots and the leading coefficient, all the coefficients are sums and products of roots. You might remember when factoring quadratics that the coefficient of x term is the sum of the two roots. These rules are called Vieta's formulas.

So, if we have the constant term, we can check all of its integer factors to see if any are roots. For each root, we can divide, using a technique like synthetic division, to continue finding the rest of the roots. This method is especially useful on tests because the roots tend to be integers.

Example. Factor the polynomial $x^5 + x^4 - 2x^3 + 4x^2 - 24x$.

We can immediately see that there is no constant term, so $x = 0$ is a root. Now we need to work on factoring $x^4 + x^3 - 2x^2 + 4x - 24$.

The factors of -24 are: -24, -12, -8, -6, -4, -3, -2, -1, 1, 2, 3, 4, 6, 8, 12, and 24. Starting from roots close to 0 and working outwards, we find that $x = 2$ is a root. So, we synthetic divide like so

$$\begin{array}{r|rrrrr} x = 2 & 1 & 1 & -2 & 4 & -24 \\ & \downarrow & 2 & 6 & 8 & 24 \\ \hline & 1 & 3 & 4 & 12 & 0 \end{array}$$

to see that now we need to work on factoring $x^3 + 3x^2 + 4x + 12$. $x^3 + 3x^2 + 4x + 12 = x^2(x + 3) + 4(x + 3) = (x + 3)(x^2 + 4)$, so $x = -3$ is a root, and we need to work on factoring $x^2 + 4$. $x^2 + 4$ has two complex roots $\pm 2i$, so we'll leave it as a quadratic.

$$x^5 + x^4 - 2x^3 + 4x^2 - 24x = x(x - 2)(x + 3)(x^2 + 4)$$

0.1.6 Trig Functions & The Unit Circle

Imagine a circle of radius 1 centered at the origin that we'll call the unit circle. The x and y coordinates of a point on the unit circle are completely determined by the angle θ in radians between the

x -axis and a line from the origin to the point.

The function $\cos \theta$ tells us x -coordinate of the point, while $\sin \theta$ tells us the y -coordinate of the point. The function $\tan \theta = \frac{\sin \theta}{\cos \theta}$ tells us the slope of the line from the origin to the point. Most of the trig functions have geometric interpretations as shown below. The most used ones are \sin , \cos , $\tan = \frac{\sin}{\cos}$, $\cot = \frac{\cos}{\sin}$, $\csc = \frac{1}{\sin}$, and $\sec = \frac{1}{\cos}$.

Figure 1: Wikipedia - Unit circle

We can also think about the inverses of these trig functions. These are either notated with a -1 exponent on the function, or the prefix arc in front of the function name. Many of these functions are only defined on a part of the domain $[0, 2\pi]$. Below is a table of the inverse trig functions and their domains.

Function	Domain
\arcsin	$[-1, 1]$
\arccos	$[-1, 1]$
\arctan	$(-\infty, \infty)$
arccot	$(-\infty, \infty)$
arccsc	$(-\infty, -1] \cup [1, \infty)$
arcsec	$(-\infty, -1] \cup [1, \infty)$

0.1.7 Trig Identities

As we could see in Figure 0.1.6, \sin and \cos form a right triangle with hypotenuse 1. So, using the Pythagorean Theorem,

$$\sin^2 \theta + \cos^2 \theta = 1.$$

By dividing by \sin^2 or \cos^2 , we can also get

$$1 + \cot^2 \theta = \csc^2 \theta \text{ and } \tan^2 \theta + 1 = \sec^2 \theta.$$

Together, these 3 identities are called the Pythagorean Identities.

We can also relate functions and co-functions.

$$\sin(\theta) = \cos\left(\frac{\pi}{2} - \theta\right).$$

Some of the most useful and used identities are the sum and difference.

$$\begin{aligned}\sin(\alpha \pm \beta) &= \sin \alpha \cos \beta \pm \cos \alpha \sin \beta \\ \cos(\alpha \pm \beta) &= \cos \alpha \cos \beta \mp \sin \alpha \sin \beta \\ \tan(\alpha \pm \beta) &= \frac{\tan \alpha \pm \tan \beta}{1 \mp \tan \alpha \tan \beta} \\ \sin \alpha \pm \sin \beta &= 2 \sin\left(\frac{\alpha \pm \beta}{2}\right) \cos\left(\frac{\alpha \mp \beta}{2}\right) \\ \cos \alpha + \cos \beta &= 2 \cos\left(\frac{\alpha + \beta}{2}\right) \cos\left(\frac{\alpha - \beta}{2}\right) \\ \cos \alpha - \cos \beta &= -2 \sin\left(\frac{\alpha + \beta}{2}\right) \sin\left(\frac{\alpha - \beta}{2}\right)\end{aligned}$$

0.1.8 Exponentials & Logarithms

Definition. e is the base of the natural logarithm. It's defined by the limit

$$e = \lim_{n \rightarrow \infty} \left(1 + \frac{1}{n}\right)^n.$$

$\exp x = e^x$ and $\ln x$ are inverse functions of each other such that

$$e^{\ln x} = x \text{ and } \ln e^x = x.$$

Just like other exponentials, the normal rules for adding, subtracting, and multiplying exponents apply:

$$e^x e^y = e^{x+y}, \frac{e^x}{e^y} = e^{x-y}, \text{ and } (e^x)^k = e^{xk}.$$

Similar rules apply for logarithms:

$$\ln x + \ln y = \ln xy, \ln x - \ln y = \ln\left(\frac{x}{y}\right), \text{ and } \ln(a^b) = b \ln a.$$

We can also write a logarithm of any base using natural logarithms:

$$\log_b a = \frac{\ln a}{\ln b}.$$

e is also unique in that it is the only real number a satisfying the equation

$$\frac{d}{dx} a^x = a^x,$$

meaning e^x is its own derivative.

0.1.9 Partial Fractions

If we have a function of two polynomials $f(x) = \frac{P(x)}{Q(x)}$, it's often easier to break this quotient into a sum of parts where the denominator is a linear or quadratic factor and the numerator is always a smaller degree than the denominator.

Example.

$$\frac{2x - 1}{x^3 - 6x^2 + 11x - 6} = \frac{1/2}{x - 1} + \frac{-3}{x - 2} + \frac{5/2}{x - 3}.$$

One natural way to find these small denominators comes from the linear factors of the denominator where we keep quadratics with complex roots. This way, when making a common denominator, we get back the original big denominator. However, there are a few special cases we have to take care of.

Linear Factors

This is the the most basic type where the degree of the numerator is less than the degree of the denominator and the denominator factors into all linear factors with no repeated roots. In this case we can write

$$\frac{P(x)}{Q(x)} = \frac{A_1}{(x - a_1)} + \dots + \frac{A_n}{(x - a_n)}.$$

Multiplying each side by $Q(x)$,

$$P(x) = A_1(x - a_2) \dots (x - a_n) + \dots + A_n(x - a_1) \dots (x - a_{n-1}).$$

We can then find each A_i by evaluating both sides at $x = a_i$, since every term except the i th has an $(x - a_i)$ factor that will go to 0. So,

$$A_i = \frac{P(a_i)}{(x - a_i) \dots (x - a_{i-1})(x - a_{i+1}) \dots (x - a_n)}.$$

Example. Find the partial fraction decomposition of the following expression:

$$\frac{2x - 1}{x^3 - 6x^2 + 11x - 6}.$$

Factoring,

$$x^3 - 6x^2 + 11x - 6 = (x - 1)(x - 2)(x - 3).$$

So,

$$\frac{2x - 1}{x^3 - 6x^2 + 11x - 6} = \frac{A_1}{x - 1} + \frac{A_2}{x - 2} + \frac{A_3}{x - 3}.$$

Multiplying each side by the denominator,

$$2x - 1 = A_1(x - 2)(x - 3) + A_2(x - 1)(x - 3) + A_3(x - 1)(x - 2).$$

At $x = 1$,

$$1 = A_1(1 - 2)(1 - 3) \implies A_1 = \frac{1}{2}.$$

At $x = 2$,

$$3 = A_2(2 - 1)(2 - 3) \implies A_2 = -3.$$

At $x = 3$,

$$5 = A_3(3 - 1)(3 - 2) \implies A_3 = \frac{5}{2}.$$

So,

$$\frac{2x - 1}{x^3 - 6x^2 + 11x - 6} = \frac{1/2}{x - 1} + \frac{-3}{x - 2} + \frac{5/2}{x - 3},$$

just as was shown in the previous example.

Repeated Linear Factors

If $Q(x)$ has repeated roots, it factors into

$$Q(x) = R(x)(x - a)^k, k \geq 2 \text{ and } R(a) \neq 0.$$

When making the common denominator for each repeated root of multiplicity k , we do

$$\frac{P(x)}{R(x)(x - a)^k} = (\text{Decomposition of } R(x)) + \frac{A_1}{x - a} + \dots + \frac{A_k}{(x - a)^k}.$$

You would then multiply each side by the denominator like in the linear factors case and solve for the coefficients. The only additional difficulty is that you might have to use previous results or solve a system of linear equations to get some of the constants.

Example. Find the partial fraction of the following expression:

$$\frac{x^2 + 5x - 6}{x^3 - 7x^2 + 16x - 12}.$$

Factoring,

$$x^3 - 7x^2 + 16x - 12 = (x - 3)(x - 2)^2.$$

So,

$$\frac{x^2 + 5x - 6}{x^3 - 7x^2 + 16x - 12} = \frac{A_1}{x - 3} + \frac{A_2}{x - 2} + \frac{A_3}{(x - 2)^2}.$$

Multiplying each side by the denominator,

$$x^2 + 5x - 6 = A_1(x - 2)^2 + A_2(x - 2)(x - 3) + A_3(x - 3).$$

At $x = 2$,

$$8 = A_3(2 - 3) \implies A_3 = -8.$$

At $x = 3$,

$$18 = A_1(3 - 2)^2 \implies A_1 = 18.$$

Now we'll use our results for A_1 and A_3 to find A_2 using a value for x that isn't 2 or 3 so the A_2 term doesn't become 0. A good choice is $x = 0$.

At $x = 0$,

$$-6 = 18(0 - 2)^2 + A_2(0 - 2)(0 - 3) + -8(0 - 3) \implies A_2 = -17.$$

So,

$$\frac{x^2 + 5x - 6}{x^3 - 7x^2 + 16x - 12} = \frac{18}{x - 3} - \frac{17}{x - 2} - \frac{8}{(x - 2)^2}.$$

Quadratic Factors

If a quadratic doesn't have real roots, then we have a quadratic factor. Here, we'll assume that the quadratic factor isn't repeated. So, $Q(x) = R(x)(ax^2 + bx + c)$, $b^2 - 4ac < 0$, and $R(x)$ is not evenly divisible by $ax^2 + bx + c$. In this case, we say

$$\frac{P(x)}{R(x)(ax^2 + bx + c)} = (\text{Decomposition of } R(x)) + \frac{A_1x + B_1}{ax^2 + bx + c}.$$

We then solve for the constants in the numerator, possibly having to solve a system of equations or using previous results and less convenient values for x .

Example. Find the partial fraction decomposition of the following expression:

$$\frac{6x^2 + 21x + 11}{x^3 + 5x^2 + 3x + 15}.$$

Factoring,

$$x^2 + 5x^2 + 3x + 15 = (x + 5)(x^2 + 3).$$

So,

$$\frac{6x^2 + 21x + 11}{x^3 + 5x^2 + 3x + 15} = \frac{A_1}{x + 5} + \frac{A_2x + B_2}{x^2 + 3}.$$

Multiplying each side by the denominator,

$$6x^2 + 21x + 11 = A_1(x^2 + 3) + (A_2x + B_2)(x + 5).$$

At $x = -5$,

$$56 = 28A_1 \implies A_1 = 2.$$

Now we'll use the previous result and another value for x . We can use $x = 0$ to not have to worry about the A_2 term. At $x = 0$,

$$11 = 2(3) + (B_2)(5) \implies B_2 = 1.$$

Now we'll use the previous 2 results to find A_2 . $x = 1$ is a good choice to keep the numbers small. At $x = 1$,

$$38 = 2(1 + 3) + (A_2 + 1)(6) \implies A_2 = 4.$$

So,

$$\frac{6x^2 + 21x + 11}{x^3 + 5x^2 + 3x + 15} = \frac{2}{x + 5} + \frac{4x + 1}{x^2 + 3}.$$

Repeated Quadratic Factors

If a quadratic factor that can't be broken into linear factors is repeated, then we can write $Q(x) = R(x)(ax^2 + bx + c)^k$, $k \geq 0$, and $R(x)$ is not divisible by $(ax^2 + bx + c)^k$. Now we have to do a combination of what we did for repeated linear factors and quadratic factors. We say

$$\frac{P(x)}{R(x)(ax^2 + bx + c)^k} = (\text{Decomposition of } R(x)) + \frac{A_1x + B_1}{ax^2 + bx + c} + \dots + \frac{A_kx + B_k}{(ax^2 + bx + c)^k}.$$

We then solve for the coefficients in the numerator.

Example. Find the partial fraction decomposition of $\frac{3x^4 - 2x^3 + 6x^2 - 3x + 3}{x^5 + 3x^4 + 4x^3 + 12x^2 + 4x + 12}$.

Factoring,

$$x^5 + 3x^4 + 4x^3 + 12x^2 + 4x + 12 = (x + 3)(x^2 + 2)^2.$$

So,

$$\frac{3x^4 - 2x^3 + 6x^2 - 3x + 3}{x^5 + 3x^4 + 4x^3 + 12x^2 + 4x + 12} = \frac{A_1}{x + 3} + \frac{A_2x + B_2}{x^2 + 2} + \frac{A_3x + B_3}{(x^2 + 2)^2}.$$

Multiplying each side by the denominator,

$$3x^4 - 2x^3 + 6x^2 - 3x + 3 = A_1(x^2 + 2)^2 + (A_2x + B_2)(x^2 + 2)(x + 3) + (A_3x + B_3)(x + 3).$$

At $x = -3$,

$$363 = 121A_1 \implies A_1 = 3.$$

Now, we'll use our result for A_1 and pick a value for x that minimizes the number of things we need to solve for. We'll have to solve a linear system with 4 unknowns, so we'll need up to 4 values. At $x = 0$,

$$3 = 3(2)^2 + B_2(2)(3) + B_3(3) \implies 2B_2 + B_3 = -3.$$

At $x = 1$,

$$7 = 3(3)^2 + (A_2 + B_2)(3)(4) + (A_3 + B_3)(4) \implies 3A_2 + A_3 + 3B_2 + B_3 = -5.$$

At $x = -1$,

$$17 = 3(3)^2 + (-A_2 + B_2)(3)(2) + (-A_3 + B_3)(2) \implies -3A_2 - A_3 + 3B_2 + B_3 = -5.$$

At $x = 2$,

$$53 = 3(6)^2 + (2A_2 + B_2)(6)(5) + (2A_3 + B_3)(5) \implies 12A_2 + 2A_3 + 6B_2 + B_3 = -11.$$

Now we have the following system of equations:

$$\begin{cases} 0A_2 + 0A_3 + 2B_2 + B_3 &= -3 \\ 3A_2 + A_3 + 3B_2 + B_3 &= -5 \\ -3A_2 - A_3 + 3B_2 + B_3 &= -5 \\ 12A_2 + 2A_3 + 6B_2 + B_3 &= -11 \end{cases}.$$

Solving,

$$A_2 = 0, A_3 = 0, B_2 = -2, \text{ and } B_3 = 1.$$

So,

$$\frac{3x^4 - 2x^3 + 6x^2 - 3x + 3}{x^5 + 3x^4 + 4x^3 + 12x^2 + 4x + 12} = \frac{3}{x+3} - \frac{2}{x^2+2} + \frac{1}{(x^2+2)^2}.$$

Improper Fractions

If the degree of the numerator is greater than or equal to the degree of the denominator, we have a case of improper fractions. In this case, we have to do polynomial long division to get a quotient and remainder and then decompose the remainder if necessary. So,

$$\frac{P(x)}{Q(x)} = R(x) + \frac{S(x)}{Q(x)}.$$

Example. Find the partial fraction decomposition of the following expression:

$$\frac{x^3 + 3}{x^2 - 2x - 3}.$$

First we do polynomial long division to find that

$$\frac{x^3 + 3}{x^2 - 2x - 3} = x + 2 + \frac{7x + 9}{x^2 - 2x - 3}.$$

Now that the numerator is of a lesser degree than the denominator, we can decompose it normally.

$$x^2 - 2x - 3 = (x - 3)(x + 1).$$

So,

$$\frac{7x + 9}{x^2 - 2x - 3} = \frac{A_1}{x - 3} + \frac{A_2}{x + 1}.$$

Multiplying each side by the denominator,

$$7x + 9 = A_1(x + 1) + A_2(x - 3).$$

At $x = -1$,

$$2 = -4A_2 \implies A_2 = \frac{-1}{2}.$$

At $x = 3$,

$$30 = 4A_1 \implies A_1 = \frac{15}{2}.$$

So,

$$\frac{x^3 + 3}{x^2 - 2x - 3} = x + 2 + \frac{15/2}{x - 3} + \frac{-1/2}{x + 1}.$$

0.2 Single Variable Calculus

0.2.1 Derivatives and Integrals

Derivatives

The derivative of a function $y = f(x)$, notated $f'(x)$, gives the slope of the tangent line to f at x .

Definition.

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x + h) - f(x)}{h}$$

Below are some properties of the derivative. Let f and g be functions of x and p a scalar.

Linearity

$$(pf \pm g)' = pf' \pm g'$$

Product Rule

$$(fg)' = f'g + fg'$$

Quotient Rule

$$\left(\frac{f}{g}\right)' = \frac{f'g - fg'}{g^2}$$

Chain Rule

$$(f \circ g)' = (f' \circ g) \cdot g'$$

Power Rule

$$\frac{dx^x}{dp} = px^{p-1}, p \neq 0$$

Exponent Rule

$$\frac{dx^x}{dp} = p^x \ln p, p > 0$$

The Power Rule and Exponent Rule are two cases of the same rule

$$\frac{d}{dx} f^g = g f^{g-1} f' + f^g \ln f g'.$$

Using the definition of the derivative and these rules, we can find the derivatives to some common functions.

$$\begin{array}{l|l} \frac{d}{dx} p = 0 & \frac{d}{dx} e^x = e^x \\ \frac{d}{dx} \ln x = \frac{1}{x} & \frac{d}{dx} \sin x = \cos x \\ \frac{d}{dx} \cos x = -\sin x & \frac{d}{dx} \tan x = \sec^2 x \end{array}$$

Integrals

The definite integral of a function $f(x)$ from $x = a$ to $x = b$ where $a \leq b$ is the area between $f(x)$ and the x -axis bounded by the lines $x = a$ and $x = b$ where area above the x -axis is positive, and area below the x -axis is negative.

Definition.

$$\int_a^b f(x) dx = \lim_{h \rightarrow 0} \sum_{n=1}^{\frac{b-a}{h}} f(a + (n-1)h) \cdot h.$$

We also define an indefinite integral, or antiderivative of $f(x)$, notated $F(x)$ where

$$F'(x) = f(x) \implies \int f(x) dx = F(x).$$

Note that there are infinitely many such functions F , since adding a constant to F does not affect its derivative. To notate this, we add a constant C to the indefinite integral. Given an initial condition for f , we can solve for C .

Below are some properties of the integral. Let f and g be functions of x and p , a , b , and c where $a < b < c$, and f and g are continuous on the closed interval $[a, c]$.

Linearity

$$\int (pf \pm g)dx = p \int fdx \pm \int gdx$$

Flipped Bounds

$$\int_a^b fdx = - \int_b^a fdx$$

Union of Intervals

$$\int_a^b fdx + \int_b^c fdx = \int_a^c fdx$$

Power Rule

$$\int x^n dx = \frac{x^{n+1}}{n+1} + C, n \neq -1$$

U-Substitution

$$\int (f' \circ g) g' dx = f \circ g + C$$

Integration by Parts

$$\int f' g dx = fg - \int fg' dx$$

Fundamental Theorem of Calculus

$$\frac{d}{dx} \int_a^x f(s) ds = f(x)$$

Using the definition of the integral and the above rules, we can find the indefinite integral of some common functions.

$$\begin{aligned}\int \frac{1}{x} dx &= \ln |x| + C \\ \int \sin x dx &= -\cos x + C \\ \int \cos x dx &= \sin x + C \\ \int \tan x dx &= -\ln |\cos x| + C\end{aligned}$$

0.2.2 Taylor Series

A Taylor series is a way of approximating a function about a point $x = a$ using polynomials. The first approximation just keeps the same value at $x = a$, the second approximation keeps the same value and first derivative at $x = a$, etc.

Definition.

$$f(x) = f(a) + f'(a)(x - a) + \frac{f''(a)}{2!}(x - a)^2 + \dots + \frac{f^{(n)}(a)}{n!}(x - a)^n + \dots$$

If we approximate a function about $x = 0$, we call this a Maclaurin series. Below are some common Maclaurin series, and their radii of convergence if applicable.

$$\begin{aligned}e^x &= 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots \\ \sin x &= x - \frac{x^3}{3!} + \frac{x^5}{5!} - \dots \\ \cos x &= 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \dots \\ \frac{1}{1+x} &= 1 - x + x^2 - \dots, \text{ where } |x| < 1 \\ \ln(1+x) &= x - \frac{x^2}{2} + \frac{x^3}{3} - \dots, \text{ where } |x| < 1\end{aligned}$$

Euler's Identity

Let's see what happens when we look at the Maclaurin series for e^{ix} .

$$\begin{aligned}e^{ix} &= 1 + (ix) + \frac{(ix)^2}{2!} + \frac{(ix)^3}{3!} + \frac{(ix)^4}{4!} + \frac{(ix)^5}{5!} \dots \\ &= 1 + ix - \frac{x^2}{2!} - i\frac{x^3}{3!} + \frac{x^4}{4!} + i\frac{x^5}{5!} - \dots \\ &= \left(1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \dots\right) + i\left(x - \frac{x^3}{3!} + \frac{x^5}{5!} - \dots\right).\end{aligned}$$

The two expressions in parenthesis are exactly the Maclaurin series for $\cos x$ and $\sin x$. So,

$$e^{ix} = \cos x + i \sin x.$$

In the case that $x = \pi$,

$$e^{i\pi} = \cos \pi + i \sin \pi = -1 + 0.$$

So,

$$e^{i\pi} + 1 = 0.$$

Chapter 1

Vector Spaces

1.1 Binary Operations

1.1.1 Definition & Notations

Definition. For some domain D , A binary operation is a function $f : D \times D \rightarrow D$. That is, it combines two elements of D to produce another element of D .

You’ve already been working with binary operations since elementary school.

Example. The following are binary operations with domain \mathbb{R} .

- Addition (+)
- Multiplication (\times)

Subtraction ($-$) is also a binary operation on \mathbb{R} . It is just a special case of addition, since for all $a, b \in \mathbb{R}$, $a - b = a + (-b)$, and $-b \in \mathbb{R}$.

One needs to specify over which domain a function is a binary operation. Functions can be binary operations over some domains but not others.

Example.

- Division (\div) is not a binary operation on \mathbb{R} since $0 \in \mathbb{R}$, but dividing by 0 is not defined. However if we consider the domain $\mathbb{R} \setminus \{0\}$, then division is a binary operation, since we no longer have to worry about dividing by 0.
- Although we saw that subtraction was a binary operation over \mathbb{R} , it is not over $D = \{x \in \mathbb{R} \mid x \geq 0\}$ because $1, 2 \in D$, but $1 - 2 = -1 \notin D$.

For many binary operations, we tend to abandon function notation in favor of an “infix” notation. For example, we write $a + b$ or $a \times b$ rather than $+(a, b)$ or $\times(a, b)$. Sometimes, if the operation is clear from context, we may drop the symbol for the operation entirely and just write the inputs next to each other. For example, if $a, b \in \mathbb{R}$, then ab is understood to mean $a \times b$.

1.1.2 Properties

A binary operation may have certain useful properties. Let \circ and \square be two binary operations with the same domain. Let a , b , and c be elements of the domain.

- **Commutative:** $a \circ b = b \circ a$
- **Associative:** $(a \circ b) \circ c = a \circ (b \circ c)$
- **Distributive over \square :** $a \circ (b \square c) = (a \circ b) \square (a \circ c)$
- **Identity:** There exists I in the domain such that $a \circ I = a = I \circ a$
- **Inverse:** There exists a^{-1} in the domain such that $a \circ a^{-1} = I = a^{-1} \circ a$

Many of the binary operations you're already familiar with satisfy some of these properties.

Example.

- *Addition over \mathbb{R} is commutative and associative. Its identity element is 0, and the inverse of a is $-a$.*
- *Multiplication over \mathbb{R} is commutative and associative. It is distributive over addition. Its identity element is 1. It is not invertable, since 0 doesn't have an inverse.*
- *Division over $\mathbb{R} \setminus \{0\}$ is not commutative, since $1/2 \neq 2/1$. It is not associative, since $(1 \div 2) \div 3 = 1/6 \neq 1 \div (2 \div 3) = 3/2$.*

1.2 Euclidean Vectors

1.2.1 Definition & Notations

Definition. A Euclidean vectors is a finite, ordered list of real numbers. Each entry in the vector is called a component. The number of components in a vector is called its dimension. The set of all Euclidean vectors with dimension n is notated \mathbb{R}^n and called "Euclidean n -space".

Often, vectors are written in square brackets with their components ordered vertically from top to bottom. We tend to symbolically represent some vector by a symbol with an arrow above it. We can represent a certain component of a vector with a subscript.

Example. The vector $\vec{v} = \begin{bmatrix} 4 \\ 5 \end{bmatrix}$ is a vector in \mathbb{R}^2 . The components are $\vec{v}_1 = 4$ and $\vec{v}_2 = 5$. Since \vec{v} can be visualized as a straight arrow in the 2D plane with its tail at the origin and its tip at $(4, 5)$, we might also notate the x and y components as $\vec{v}_x = 4$ and $\vec{v}_y = 5$.

Figure 1.1: The x and y components of a vector v

1.2.2 Properties

We can define addition and scalar multiplication of Euclidean vectors.

Definition. Let $\vec{a}, \vec{b} \in \mathbb{R}^n$ and $c \in \mathbb{R}$ then

1.

$$\vec{a} + \vec{b} = [a_i + b_i \mid i \in \{1, 2, \dots, n\}],$$

2.

$$c \cdot \vec{a} = [c \cdot a_i \mid i \in \{1, 2, \dots, n\}].$$

Example. Let $\vec{u} = \begin{bmatrix} 1 \\ -2 \\ 3 \end{bmatrix}$, $\vec{v} = \begin{bmatrix} -1 \\ 4 \\ 3 \end{bmatrix}$, and $\vec{w} = \begin{bmatrix} 4 \\ 2 \\ 6 \end{bmatrix}$. Then

$$\begin{aligned} (2\vec{u} + \vec{v}) - 3\vec{w} &= \left(2 \begin{bmatrix} 1 \\ -2 \\ 3 \end{bmatrix} + \begin{bmatrix} -1 \\ 4 \\ 3 \end{bmatrix} \right) - 3 \begin{bmatrix} 4 \\ 2 \\ 6 \end{bmatrix} \\ &= \left(\begin{bmatrix} 2 \\ -4 \\ 6 \end{bmatrix} + \begin{bmatrix} -1 \\ 4 \\ 3 \end{bmatrix} \right) + \begin{bmatrix} -12 \\ -6 \\ -18 \end{bmatrix} \\ &= \begin{bmatrix} 1 \\ 0 \\ 9 \end{bmatrix} + \begin{bmatrix} -12 \\ -6 \\ -18 \end{bmatrix} \\ &= \begin{bmatrix} -11 \\ -6 \\ -9 \end{bmatrix}. \end{aligned}$$

Notice that addition of vectors is a binary operation over \mathbb{R}^n . Also, many of the properties we said binary operations could have are satisfied.

Theorem. *The addition of two vectors in \mathbb{R}^n is commutative and associative. The identity vector is the one containing all 0's. The inverse of any vector \vec{v} is $-1 \cdot \vec{v} = -\vec{v}$. Vector-scalar multiplication¹ is distributive over vector addition.*

1.3 Abstract Vector Spaces

1.3.1 Definition

Definition. *A set V is a vector space of a field F (for us, \mathbb{R} or \mathbb{C}) provided that the operations $\oplus : V \times V \rightarrow V$, called “addition”, and $\odot : V \times F \rightarrow V$, called “scalar multiplication”, are defined and satisfy the following for all $\vec{u}, \vec{v}, \vec{w} \in V$ and $a, b \in F$:*

Addition Properties

1. **Commutative:** $\vec{u} \oplus \vec{v} = \vec{v} \oplus \vec{u}$
2. **Associative:** $\vec{u} \oplus (\vec{v} \oplus \vec{w}) = (\vec{u} \oplus \vec{v}) \oplus \vec{w}$
3. **Additive Identity:** *There exists $\vec{0} \in V$ such that for all $\vec{u} \in V$, $\vec{u} \oplus \vec{0} = \vec{u}$.*
4. **Additive Inverse:** *For each $\vec{u} \in V$, there exists $-\vec{u} \in V$ such that $\vec{u} \oplus -\vec{u} = \vec{0}$.*

Multiplication Properties

1. **Multiplicative Identity:** *There exists $1 \in F$ such that for all $\vec{u} \in V$, $1 \odot \vec{u} = \vec{u}$.*

Distributive Properties

1. **Left Distributes Over \oplus :** $a \odot (\vec{u} \oplus \vec{v}) = (a \odot \vec{u}) \oplus (a \odot \vec{v})$
2. **Right Distributes Over \oplus :** $(\vec{u} \oplus \vec{v}) \odot a = (\vec{u} \odot a) \oplus (\vec{v} \odot a)$
3. **Distributes Over Field Multiplication:** $(ab) \odot \vec{u} = a \odot (b \odot \vec{u})$

Here are a few examples of vector spaces:

Example.

- \mathbb{R}^n with operations of vector addition and vector-scalar multiplication over the field \mathbb{R}
- \mathbb{R}^2 where

$$\begin{bmatrix} u_1 \\ u_2 \end{bmatrix} \oplus \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} u_1 + v_1 + 1 \\ u_2 + v_2 + 1 \end{bmatrix} \text{ and } a \odot \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \begin{bmatrix} au_1 + 1 \\ au_2 - 1 \end{bmatrix}$$

¹Vector-scalar multiplication is not a binary operation, but the distributive property still holds

- All polynomials of degree n with real coefficients
- \mathbb{Q} over the field \mathbb{Q}
- All real functions that are continuous on $[0, 1]$

Not all operations for \oplus and \odot will result in vector spaces.

Example. \mathbb{R} where

$$a \oplus b = 2a + 2b \text{ and } k \odot a = ka$$

is not a vector space because

$$\begin{aligned} 2 \oplus (3 \oplus 4) &= 2 \oplus 14 = 32, \\ (2 \oplus 3) \oplus 4 &= 10 \oplus 4 = 28, \end{aligned}$$

so \oplus isn't associative.

1.3.2 Properties

Here are several useful properties of vector spaces. Most of these likely seem intuitively true.

Let $(V, +, \cdot)$ be a vector space.

Theorem. *The additive identity is unique.*

Proof. We will show that any two elements of V that behave like the additive identity must be equal. Suppose V has two additive identities $\vec{0}$ and $\vec{0}'$. Since both are additive identities,

$$\begin{aligned} \vec{0} &= \vec{0} + \vec{0}' \\ \vec{0}' &= \vec{0} + \vec{0}'. \end{aligned}$$

Since the expressions on the right of each line are equal, the expressions on the left must also be equal. So $\vec{0} = \vec{0}'$, as desired. ■

Theorem. *The additive inverse of an element is unique.*

Proof. Suppose \vec{v} and \vec{v}' are both additive inverses of \vec{u} . Then

$$\begin{aligned} \vec{u} + \vec{v}' &= \vec{0} \text{ and } \vec{u} + \vec{v} = \vec{0} \\ \vec{v} &= \vec{v} + \vec{0} \\ &= \vec{v} + (\vec{u} + \vec{v}') \\ &= (\vec{v} + \vec{u}) + \vec{v}' \\ &= \vec{0} + \vec{v}' \\ &= \vec{v}', \end{aligned}$$

as desired. ■

Theorem. For all $\vec{v} \in V$, $0 \cdot \vec{v} = \vec{0}$.

Proof. Notice that

$$\begin{aligned} 0 \cdot \vec{v} &= (0 + 0) \cdot \vec{v} \\ &= 0 \cdot \vec{v} + 0 \cdot \vec{v}. \end{aligned}$$

Let \vec{w} be the additive inverse of $0 \cdot \vec{v}$. Then

$$\begin{aligned} 0 \cdot \vec{v} + \vec{w} &= 0 \cdot \vec{v} + 0 \cdot \vec{v} + \vec{w} \\ \vec{0} &= 0 \cdot \vec{v} + \vec{0} \\ \vec{0} &= 0 \cdot \vec{v}, \end{aligned}$$

as desired. ■

Theorem. For all $a \in \mathbb{R}$, $a \cdot \vec{0} = \vec{0}$.

Proof. Notice that

$$\begin{aligned} a \cdot \vec{0} &= a \cdot (\vec{0} + \vec{0}) \\ &= a \cdot \vec{0} + a \cdot \vec{0}. \end{aligned}$$

Let \vec{w} be the additive inverse of $a \cdot \vec{0}$. Then

$$\begin{aligned} a \cdot \vec{0} + \vec{w} &= a \cdot \vec{0} + a \cdot \vec{0} + \vec{w} \\ \vec{0} &= a \cdot \vec{0} + \vec{0} \\ \vec{0} &= a \cdot \vec{0}, \end{aligned}$$

as desired. ■

Theorem. For all $\vec{v} \in V$, $-1 \cdot \vec{v} = -\vec{v}$.

Proof. Notice,

$$\begin{aligned} -1 \cdot \vec{v} &= -1 \cdot \vec{v} + \vec{0} \\ &= -1 \cdot \vec{v} + (\vec{v} - \vec{v}) \\ &= (-1 \cdot \vec{v} + \vec{v}) - \vec{v} \\ &= (-1 + 1) \vec{v} - \vec{v} \\ &= \vec{0} - \vec{v} \\ &= -\vec{v}, \end{aligned}$$

as desired. ■

1.3.3 Subspaces

Definition. A non-empty subset U of a vector space V is a subspace of V if U is a vector space with the operations inherited from V .

Here are a few examples of subspaces:

Example.

- The set of vectors $\left\{ \begin{bmatrix} x \\ y \\ 0 \end{bmatrix} \mid x, y \in \mathbb{R} \right\}$ is a subspace of \mathbb{R}^3 .
- The set of real-valued functions $\{f \in \mathbb{R}^{[0,1]} \mid \int_0^1 f(x)dx = 0\}$ is a subspace of all real-valued functions that are integrable over $[0, 1]$, $\mathbb{R}^{[0,1]}$.
- The set of functions $\{f : [0, 1] \rightarrow \mathbb{R} \mid f'(1/2) = 0\}$ is a subspace of $\mathbb{R}^{[0,1]}$.

Here are a few non-examples of subspaces:

Example.

- The set of vectors $W = \left\{ \begin{bmatrix} x \\ y \\ z \end{bmatrix} \mid x, y, z \in \mathbb{R}, 2x + y - z = -4 \right\}$ is not a subspace of \mathbb{R}^3 because $\vec{0} \notin W$, meaning there is no additive identity.
- The set of real-valued functions $\{f \in \mathbb{R}^{[0,1]} \mid \int_0^1 f(x)dx = 1\}$ is not a subspace of $\mathbb{R}^{[0,1]}$ because it is not closed under addition.
- The set of functions $\{f : [0, 1] \rightarrow \mathbb{R} \mid f'(1/2) = 1\}$ is not a subspace of $\mathbb{R}^{[0,1]}$ because it is not closed under scalar multiplication.

It would be tedious to recheck all the vector space conditions when seeing if a set is a subspace. Thankfully, we have an easier subspace test

Theorem. Let U be a non-empty subset of a vector space V . U is a subspace of V if and only if U is closed under addition and scalar multiplication.

Proof. Assume that U is closed under addition and scalar multiplication. Since $U \subseteq V$, the addition properties of commutativity and associativity hold, the multiplicative identity is in U , and the distributive properties all hold. Thus, all that remains to check is whether the additive inverse exists, and whether each element of U has an additive inverse.

Let $\vec{u} \in U$. Since $U \subset V$ and V is a vector space, there exists $-\vec{u} \in V$. By previous result, we know that $-\vec{u} = -1 \cdot \vec{u}$. Since U is closed under scalar multiplication, $-\vec{u} \in U$. Further, since $\vec{u} + (-\vec{u}) = \vec{0}$, and U is closed under addition, $\vec{0} \in U$. ■
